The Running Coupling from the Quark–Gluon Vertex

Jon Ivar Skullerud

We present results for the QCD running coupling obtained from measuring the quark-gluon vertex in Landau gauge with suitable renormalisation conditions. The issue of discretisation errors arising from the fermion action is discussed.

1. Introduction

The quark–gluon vertex is one of the fundamental quantities of QCD, and studying the form of the vertex can give us greater insights into the dynamics of the theory and may provide an important necessary input into Dyson–Schwinger equations. Here we will focus on using the quark–gluon vertex to extract the running coupling from first principles.

2. The vertex function

The full (unamputated) momentum space vertex function can be defined as

\[ G_\mu(p, q)_{\alpha\beta} = \langle S(p + q)^{-1} S(p) A_\mu^{\alpha}(p) \rangle \]

and the amputated (OPI) vertex function

\[ \Lambda_\mu^{\alpha, \text{lat}}(p, q) = \langle S(p + q)^{-1} S(p) A_\mu^{\alpha}(q) \rangle \]

where \( D(q) \) is the scalar part of the gluon propagator, given in the Landau gauge by

\[ D^{ab}(q) = \delta^{ab} T_{\mu\nu}(q) D(q) \]

where \( T_{\mu\nu} \) is the projection onto transverse fields.

Using the requirements of Lorentz covariance and parity and charge conjugation invariance, one can derive the following general form for the vertex in the continuum:

\[ \Lambda_\mu(p^2, q^2, pq) = \frac{1}{N_C - 1} \text{Tr} \cot T^3 \Lambda_\mu(p, q) \]

\[ = F_1 p_\mu + F_2 q_\mu + F_3 \gamma_\mu \]

\[ + F_4 \bar{p} p_\mu + F_5 \bar{q} q_\mu + F_6 \bar{q} p_\mu + F_7 \bar{p} q_\mu \]

\[ + F_8 \sigma_{\mu\nu} p^\nu + F_9 \sigma_{\mu\nu} q^\nu \]

\[ + F_{10} \epsilon_{\mu\nu\lambda} \gamma_5 p^\nu q^\lambda \]

where all the \( F \)'s depend only on the invariants \( p^2, q^2 \) and \( pq \).

At tree level, this reduces to \( \Lambda_{\mu}^0 = \frac{1}{2} g_0 \gamma_\mu \). From this we can see that the form factor containing the running coupling is \( F_3 \), while all the other form factors are expected to be finite.

If we define

\[ K_\mu(p, q) = i \text{Tr} \gamma_\mu \Lambda_\mu(p, q) \]

we find that \( i F_3(p^2, 0, 0) = K_\mu(p, 0)|_{p_\mu = 0} \).

This kinematics can then be used to define a momentum subtraction scheme for the renormalised coupling:

\[ g_R^{\text{MOM}}(\mu) = -2i Z_\psi Z_\Lambda^1 \langle \mu \rangle F_3(p^2, 0, 0)|_{p^2 = \mu^2} \]

where \( Z_\psi \) and \( Z_\Lambda \) are the renormalisation constants for the quark and gluon fields, defined in the Landau gauge by

\[ D(p^2)|_{p^2 = \mu^2} = Z_\Lambda(\mu) \]

\[ \text{Tr} (\gamma \bar{p}) S^{-1}(\bar{p}) |_{p^2 = \mu^2} = \frac{i}{Z_\psi(\mu)} \]

\( \bar{p}_\mu = \frac{1}{2} \sin k_\mu a \) is used in the definition of \( Z_\psi \) to make it more ‘continuum-like’.

\( g_R^{\text{MOM}} \), as defined in [1], can then be related perturbatively to the running coupling calculated in other schemes, eg. \( g_R^{\text{MS}}(q^2) \). This matching can be performed entirely within continuum perturbation theory [1].
The running of $g_{R}^{\textit{MOM}}$ can also be compared to the perturbative continuum coupling derived from the two-loop beta function

$$g^{2}(\mu) = \left[ b_{0} \ln(\mu^{2}/\Lambda^{2}) + \frac{b_{1}}{b_{0}} \ln \ln(\mu^{2}/\Lambda^{2}) \right]^{-1}$$

with $b_{0} = 11/16\pi^{2}$, $b_{1} = 102/(16\pi^{2})^{2}$, by doing a one-parameter fit to this formula.

3. Computation and results

332 quenched configurations have been analysed at $\beta = 6.0$ ($a^{-1} = 2\text{GeV}$) with a lattice size of $16^{3}\times48$. The propagators have been generated using the tadpole improved Sheikholeslami–Wohlert action, at $\kappa = 0.137$. The gauge fields and propagators have been fixed to Landau gauge, with accuracy $1/\Lambda_{\chi}(x) = \sum_{x,\mu} |\partial_{\mu}A_{\mu}(x)|^{2} < 10^{-12}$.

The full vertex $\gamma_{\mu}G_{\mu}(p, q)$ has a clear, symmetric signal for $q = 0$ and all values of $p$ where $p_{\mu} = 0$. For $q \neq 0$ the signal falls off rapidly, and disappears entirely for $|qa| \geq \frac{\pi}{4}$. This makes it difficult to implement a renormalisation scheme where $q \neq 0$, although this would be preferable.

In order to compute the proper vertex, one needs the quark renormalisation constant $Z_{\psi}$. As figure 1 shows, this suffers from serious ambiguities, especially at high momenta. A more detailed analysis shows these ambiguities to be a result of violation of rotational symmetry, which can be attributed to $O(a)$ errors in the fermion action: although the SW action is $O(a)$ improved, this is only the case for on-shell, gauge invariant quantities. In order to remove $O(a)$ errors for gauge dependent, off-shell quantities, one requires two additional counterterms in the actions $[3].$

3.1. The proper vertex and $g_{R}$

One feature of the data is the strong correlations between data at different momenta. This makes an assessment of possible violations of rotational and reflection symmetry difficult, as it turns out that different samples of 83 configurations can have values of $K_{\mu}$ as much as $3\sigma$ apart. With this proviso, we find that for $q = 0$ and $p_{\mu} = 0$, $K_{\mu}(p, q)$ is independent of $\mu$ within errors, as one would expect. For $p_{\mu} \neq 0$, the $F_{4}$ form factor appears, and this has a large effect

![Figure 1. $Z_{\psi}(\mu)$ as a function of $\mu$, for 80 configurations.](image1)

![Figure 2. $g_{R}^{\textit{MOM}}(\mu)$ as a function of $\mu$.](image2)
An estimate for $\Lambda_{QCD}$ in this scheme has been obtained by inverting equation (9), and the result is plotted as a function of momentum in figure 3. The running of $g^{MOM}_R$ will be consistent with two-loop continuum perturbation theory where this estimate is consistent with a constant. However, no firm conclusions can be drawn in this case, since the point where the data becomes consistent with a constant value for $\Lambda$ (above 1GeV) is also where noise begins to dominate.

Figure 3. $\Lambda^{MOM}$ as a function of the renormalisation scale $\mu$.

4. Discussion and conclusions

The feasibility of using the quark–gluon vertex to extract the QCD running coupling has been demonstrated, although $O(a)$ errors in the quark propagator remain a problem. This may be addressed by using an off-shell improved fermion action, but further work is needed to investigate the feasibility of this.

These results will be matched perturbatively to the $\overline{MS}$ scheme to enable a quantitative comparison with other determinations of $\alpha_s$. A study of the other form factors in the vertex, as well as the possible effects of Gribov copies, is also underway.
