# Synthesis and Coordination Studies of Novel Heteroaryl Tetrazoles 

A thesis submitted to the National University of Ireland in fulfilment of the requirements for the degree of

Doctor of Philosophy
By
Ursula Sheridan, B.Sc.

Department of Chemistry, Maynooth University, Maynooth, Co. Kildare, Éire.

September 2014

Research Supervisor: Dr. John McGinley
Head of Department: Dr. John Stephens

Dedicated to my parents, Cecilia and Patsy. Thank you for everything.

## Table of Contents

Declaration ..... i
Acknowledgements ..... ii
Abstract ..... V
List of Abbreviations ..... vi
Chapter 1: Introduction ..... 1
1.1 Introduction to Tetrazoles ..... 2
1.1.1 Bioisosteres of Carboxylic Acids - Medicinal Attributes of Tetrazoles. ..... 2
1.1.2 Synthesis of Tetrazoles ..... 3
1.1.3 Functionalisation of 5-Substituted Tetrazoles. ..... 11
1.2 Coordination Chemistry - Overview Of Topics Relevant to Thesis ..... 16
1.2.1 Crystal Field Theory ..... 16
1.2.2 Jahn-Teller Distortions ..... 19
1.3 Metals in Anti-Cancer Agents ..... 20
1.4 Metal-Organic Frameworks ..... 22
1.4.1 Historical Developments and Nomenclature. ..... 22
1.4.2 Synthesis of Coordination Polymers ..... 24
1.4.3 Post-Synthetic Modifications ..... 28
1.5 Aims of Thesis ..... 35
Chapter 2: Synthesis and Characterisation of Pyridyl Tetrazole Ligands and Their Metal Complexes. ..... 36
2.1 Introduction ..... 37
2.1.1 Inorganic Complexes in Medicinal Chemistry ..... 37
2.1.2 Metal Complexes of Tetrazoles in Biology ..... 37
2.1.3 Anti-cancer Activity of Metal Complexed Pyridyl Tetrazoles ..... 39
2.2 Aims and Objectives of Chapter ..... 42
2.3 Results and Discussion ..... 43
2.3.1 Synthesis of Ligands. ..... 43
2.3.2 Synthesis of Metal Complexes. ..... 48
2.3.3 In vivo Compound Tolerance in Galleria mellonella. ..... 66
2.4 Conclusions ..... 70
2.5 Experimental ..... 71
2.5.1 Instrumentation ..... 71
2.5.2 Synthesis of Alkylbromo Pyridyl Tetrazoles. ..... 72
2.5.3 Metal Complexation Reactions with Alkylbromo Pyridyl Tetrazoles ..... 75
2.5.4 Synthesis of Alkyl Chain Pyridyl Tetrazoles ..... 81
2.5.5 Metal Complexation Reactions with Alkyl Pyridyl Tetrazoles ..... 83
2.5.6 Synthesis of Alcohol Pyridyl Tetrazoles ..... 88
2.5.7 Metal Complexation Reactions with Alcohol Pyridyl Tetrazoles. ..... 91
Chapter 3: Ester and Carboxylate Functionalised Pyridyl Tetrazoles. ..... 96
3.1 Introduction ..... 97
3.1.1 Pyridyl Tetrazole Esters as Organic Linkers in Coordination Polymers. ..... 97
3.1.2 Rationale for Employing 3.1 and 3.2 as Organic Linkers in CPs ..... 98
3.1.3 Bi- and Multifunctional Tetrazole Based Ligands in CPs ..... 100
3.2 Aims and Objectives of Chapter. ..... 104
3.3 Results and Discussion ..... 105
3.3.1 Synthesis of the Pyridyl Tetrazole Ester Derivatives ..... 105
3.3.2 Metal Complexation Reactions. ..... 107
3.3.3 EPR Spectral Studies. ..... 129
3.3.4 Luminescent Properties of CPs. ..... 136
3.4 Conclusions ..... 141
3.5 Experimental ..... 143
3.5.1 Instrumentation ..... 143
3.5.2 $\quad$ Synthesis of 3.1 and 3.2 ..... 144
3.5.3 Synthesis of 3.1 (pytzaH) and 3.2 (pytzaH) ..... 145
3.5.4 Metal Complexation Reactions. ..... 146
Chapter 4: Dicarboxylate Functionalised Pyridyl Tetrazoles ..... 152
4.1 Introduction ..... 153
4.1.1 Asymmetric Carboxylates as Linkers in CPs ..... 154
4.2 Aims and Objectives of Chapter ..... 156
4.3 Results and Discussion ..... 158
4.3.1 $\quad$ Synthesis of Diester Pyridyl Tetrazoles 4.3 and 4.4. ..... 158
4.3.2 Metal Complexation Reactions. ..... 164
4.3.3 EPR Spectral Studies on Cu(II) Compounds ..... 182
4.3.4 Luminescence studies ..... 183
4.4 Conclusions ..... 184
4.5 Experimental ..... 186
4.5.1 Instrumentation ..... 186
4.5.2 Synthesis of Diester Pyridyl Tetrazoles 4.3 and 4.4 ..... 187
4.5.3 Metal Complexation Reactions ..... 194
4.5.4 Metal Complexation Reactions with Dicarboxylate Pyridyl Tetrazoles ..... 195
Chapter 5: Bis-Tetrazole Systems ..... 198
5.1 Introduction ..... 199
5.2 Aims and Objectives of Chapter ..... 204
5.3 Results and Discussion ..... 207
5.3.1 Synthesis of Ligands. ..... 207
5.3.2 Metal Complexation Reactions ..... 215
5.3.3 EPR Studies ..... 221
5.4 Conclusions ..... 222
5.5 Experimental ..... 224
5.5.1 Instrumentation ..... 224
5.5.2 Synthesis of Flexible Bis-Tetrazole Ligands 5.1, 5.2 and 5.3 ..... 225
5.5.3 Synthesis of Rigid Bis-Tetrazole Ligands 5.4, 5.5 and 5.6 ..... 228
5.5.4 Metal Complexation Reactions with 5.1 and 5.2 ..... 231
5.5.5 Metal Complexation Reactions of 5.4 and 5.5 ..... 231
Chapter 6: Conclusions and Future Work ..... 233
6.1 Conclusions ..... 234
References ..... 238
Appendix ..... 250

## Declaration

I hereby certify that this thesis has not been submitted before, in whole or in part, to this or any university for any degree and is, except where otherwise stated, the original work of the author.

Signed: $\qquad$ Date:

## Acknowledgements

A sincere thanks to my supervisor Dr. John McGinley for his support, advice and friendship throughout my time here. Despite your long commute to Denmark, you always dedicated the time to discuss work and new ideas, and for that I am truly grateful. It's sad to think that soon there will be no McGinley group to keep things a little colourful inside and outside of the lab. You will be truly missed in the department and I wish you all the best in the future.

Thanks to Prof. John Lowry and Dr. John Stephens for allowing me to conduct my research in the department and for their help throughout my studies. I would especially like to thank Dr. Stephens for the great opportunity to deliver lectures in the department. Thanks to all the academic staff who never refused me when I came knocking at their doors, especially Dr. Denise Rooney, Dr. Sean McCaffery and Dr. Trinidad Velasco-Torrijos. Donna and Carol, you always are so helpful anytime I call in, thanks for everything. I owe a debt of gratitude to the technical staff: Ollie, Barbara and Maryanne for all those Mass Spec. and elemental analysis samples, thank you so much for your patience and persistence; Ken for efficiency in ordering my chemicals and bartering; Ria for everything, you're an absolute saint and how you manage to do all your jobs, walk the dogs AND look after us all I'll never know; Noel, you're an invaluable asset to the department, thanks for all your help and expertise in all things IT and GAA. I am grateful to Dr. Kevin Kavanagh for allowing me to carry out G. mellonella work in his lab and for helpful advice. Thanks to Prof. Morten Bjerrum for inviting me to work in the University of Copenhagen and Dr. Constantinos Milios for the solid state fluorescence data presented in this thesis. I've worn out the road between here and DCU to Dr. John Gallagher, thanks so much for your hard work with the X-ray crystal structures and for all your advice and fruitful discussions. I am also very grateful to the IRC and the John and Pat Hume Scholarship for funding.

I leave this place with a lot of memories to cherish, and for these I have to thank my fellow postgraduates who provided so much entertainment over the years. To all the gang that was here when I started: John, Valeria, Sinead, Róisín, Declan, Denis, Rob, Lorna, Foxy, Trish, Murph, Lynn, Joey, Louise, Wayne, Carol and Colin, you were all so helpful when I was stuck with something and I'm so appreciative that you all shared your expertise so willingly when you were always so busy yourselves. To top it all off you provided a great atmosphere to work/play in! I've been so lucky to have made great friends from this experience and to this end a special thanks has to go to Lorna (for your hilarious stories,
keeping me company on the many late nights and for being a loyal friend), Declan (for that banked salmon story, the lifts and the introduction to Bhuna), Foxy (for chats and beehroo!), Valeria (for all your sweet treats, Cillian is the luckiest boy ever), Rob (Euphoria ya dope) and Róisín (for comic relief and escapes to the mobile in recent times). Ye were always up for a coffee or a pint or two (or three) and the memories we've shared (wheelbarrow race in the lab anyone?) will remain with me always. To my research group, especially Niall, Sam, Niamh and Haixin for making the West side a fun place to be. Niall thanks so much for your company and chats over the years. The building could be crashing down around you, and you'd still be cool, calm and collected, thanks for making everything 'grand'! Thanks to my lab buddy Haixin, the best word to describe you would be Gent and I still don't think that aptly describes your friendship and generosity to me over the years, thank you so so much for all the papers, help and Chinese culture lessons, thanks to you I know I better get a move on as 25 is over the hill! To all the 'newbies': Rossy Wossy, Chiggy, Barry, HANDrew, Justine, Jessica, Jack (for your boundless energy and enthusiasm), Adam (traitor), Dave, Karen, Ula, Michelle, Collette, thanks so much for the lab banter and nights out over the years. I wish you all the best in the future and hope you enjoy your time here as much as I have. Finno, thanks for our post match analysis chats, it was great to chat to someone who knew as much about football as me (tee hee!). To my writing roomie Ruth, thanks for the venting sessions, advice and distractions (namely The Daily Mail). We started out on our adventures together and it's great we've finished up together too. To everyone, you all make the place what it is and thanks for making life on the bench an enjoyable one. I hope you all know how lucky you are to have each other and please promise me that the tea room will never disappear!

I've been blessed with the most understanding and supportive family and friends. Elaine, Hannah, Donna, Charlotte, Louise, Vanessa, Aisling and Lisa, thanks so much for the comic relief and showing me what I was missing outside of the lab. Thanks for being there and encouraging me whenever it all got too much and for understanding when I couldn't join you on your adventures. I promise you will be sick of the sight of me from now on! A special thanks must go to Marian as you poor thing had to put up with me for the length of this PhD and then some! Thanks so much for the chats and for listening. You've been with me through the highs and lows of this project and I couldn't imagine doing it without you. I'm also so proud of your chemistry knowledge after all these years!

To the Walshs, for always making me feel at home and ensuring I didn't come back up to Maynooth on an empty stomach, a heartfelt thank you.

John, as much as Rob and Dec slag me, I DO realise how incredibly lucky I am to have you in my life. By right, you should be in all the previous paragraphs too, but no amount of paragraphs would ever thank you enough. You've always offered unfailing love, friendship and support and believed in me whenever I doubted myself. Words cannot express how grateful I am for that. I promise we can go on as many holidays as you want now!

A huge thank you to my Mam and Dad. Dad, I may have taken your plea to "stay in education" a little too seriously, but I hope I've made you and Mam proud. Thank you for your endless support and encouragement in everything I've ever done.

#### Abstract

This thesis describes the synthesis, characterisation and coordination studies of an array of heteroaryl 5 -substituted tetrazole ligands. A family of 5 -substituted pyridyl tetrazole ligands with various functionalities tethered to the tetrazole moiety were prepared and fully characterised. These ligands were reacted with various $\mathrm{MX}_{2}$ salts $(\mathrm{M}=\mathrm{Cu}, \mathrm{Ni}, \mathrm{Co}, \mathrm{Zn}$; $\mathrm{X}=$ chloride, thiocyanate). A number of the resulting discrete metal complexes were analysed by X-ray crystallography and their potential application as anti-cancer therapeutics are discussed.

Carboxylate functionalised pyridyl tetrazole ligands were also synthesised and characterised. These ligands were examined for their potential to form coordination polymers. These investigations have been successful and have led to a series of coordination polymers and discrete clusters, some of which were examined by X-ray crystallography. Diamagnetic materials were subjected to solid state fluorescence studies and exhibited (in all but one case) increased emission when compared to the free parent ligands. EPR spectroscopic studies were also performed on Cu(II) materials.

We proceeded to develop these ligands into dicarboxylate systems in order to achieve higher dimensional coordination polymers. This work yielded a plethora of novel 1-D coordination polymers and dinuclear clusters with $\mathrm{Cu}(\mathrm{II}), \mathrm{Ni}(\mathrm{II}), \mathrm{Co}(\mathrm{II}), \mathrm{Mn}(\mathrm{II})$ and $\mathrm{Zn}(\mathrm{II})$ as the metal ions. Interesting manifestations were observed in these investigations, including the selective hydrolysis of an alkyl ester over an aromatic ester; selective coordination of aromatic carboxylates to hard metal cations; and the presence of coordinatively vacant carboxylate sites which open exciting avenues in the field of postsynthetic modifications. X-ray crystallography was performed on ten products. EPR spectroscopy was performed on $\mathrm{Cu}(\mathrm{II})$ materials and the solid state emission spectrum of one Zn (II) complex displayed increased emission compared to its free ligand.

Continuing the theme of coordination polymers, we investigated the ability of carboxylate functionalised bis-tetrazole ligands to form coordination polymers with $\mathrm{Cu}(\mathrm{II})$. Two categories of bis-tetrazole systems were synthesised and examined: flexible linked and rigidly linked tetrazoles. Investigations of pyrazine linked tetrazoles that were functionalised with carboxylate groups led to two 2-D coordination polymers, one of which contains water clusters and thus presents future opportunities for removal or substitution of these molecules for guest uptake and future applications.

## Chapter 1: Introduction

### 1.1 Introduction to Tetrazoles

Tetrazoles are a class of organic heterocyclic compounds containing a five-membered ring composed of four nitrogen atoms and one carbon atom (Figure 1.1). An increasingly popular functionality, tetrazoles have found many uses as fragments in pharmaceutical drugs (anti-bacterial, anti-allergic, anti-inflammatory, anti-fungal), ${ }^{1}$ information recording systems and photography, not to mention a recent increase of interest in employing tetrazoles as greener explosive materials and in pyrotechnics. ${ }^{2,3}$ The tetrazole ring has had its greatest influence in the field of medicinal chemistry where it has become an important structural motif in the design of new drugs. ${ }^{1}$ This is reflected by the fact that the number of publications and patents in this field of medicinal chemistry has increased substantially in recent years. ${ }^{4}$

Figure 1.1: Basic structure of tetrazole.

### 1.1.1 Bioisosteres of Carboxylic Acids - Medicinal Attributes of Tetrazoles

The main reason tetrazoles have received particular interest in medicinal chemistry is that they constitute the most commonly used bioisostere of the carboxylic moiety. Bioisosteres are substituents or groups that impart similar biological properties to a chemical compound. The purpose of exchanging one bioisostere for another is to fine tune the pharmacokinetic or pharmacodynamic properties of a bioactive compound. There are many similarities in the properties of both tetrazole and carboxylic acid moieties. Tetrazoles contain a free N - H which is acidic in nature, having similar acidity to carboxylic acids ( $\mathrm{p} K_{\mathrm{a}} 4.5-4.9$ vs. 4.2-4.4 respectively). ${ }^{5}$ This is due to the ability of both to stabilise a negative charge by electron delocalisation. Other similarities are that tetrazoles are ionised at physiological pH and exhibit a planar structure like their carboxylic acid counterparts. There are, of course, some differences between the two moieties. Hansch has shown that anionic tetrazoles are almost 10 times more lipophilic than the corresponding carboxylic acid. ${ }^{5}$ This increased lipophilicity could account for the higher membrane permeability often seen with tetrazole bioisosteres compared to their carboxylate analogues. ${ }^{6}$ A major advantage of tetrazoles over carboxylic acids is that they are resistant to many biological metabolic degradation pathways and long half lives are seen with a
number of orally administered tetrazole containing compounds. ${ }^{7}$ Tetrazoles also have a larger surface area and a greater ability to delocalise a negative charge, which may aid in receptor-substrate interaction. This could also have a negative impact, whereby it could hinder receptor-substrate interaction due to a local charge density or sterically hindering a change in structural information to allow for binding of a receptor molecule. These observed similarities and differences make tetrazoles interesting bioisosteres which are worth studying further.

The most important group of biologically active compounds based on tetrazoles are the selective antagonists of the receptor angiotensin II. The first representative, Losartan, has been in clinical use since 1994 (Figure 1.2) ${ }^{8}$ and is a good example of a drug in which the optimal ratio of anti-hypertensive activity and per os bioavailability was achieved. Carboxylic acid analogues of this drug also possessed anti-hypertensive properties but were less active, even when they were administered intravenously. Other bioisosteric replacements of carboxylic acids were examined during the development of this drug, however, these replacements failed to display better properties than the tetrazole derivatives. ${ }^{9}$

Figure 1.2: Structure of Losartan. ${ }^{8}$

### 1.1.2 Synthesis of Tetrazoles

With the tetrazole group's increasing importance in medicinal chemistry, the efficient synthesis of tetrazole derivatives has become an important task. This pursuit of improving its synthesis was also evident in the early days of tetrazole development. In 1885, Bladin coined the term tetrazole for a five-membered heteroarene consisting of four nitrogens and proved its existence somewhat mistakenly while he was investigating the reactions of dicyanophenyl hydrazine, the condensation product of cyanogens and phenylhydrazine. Treatment of dicyanophenyl hydrazine with nitrous acid led to the first reported tetrazole containing compound, later known as 5-cyano-2-phenyltetrazole (Figure 1.3).10

Figure 1.3: The first tetrazole containing compound prepared, 5-cyano-2-phenyltetrazole.

The most interesting compounds containing tetrazole moieties are 5 -substituted tetrazoles (5-STs). The first specific and widely used methods for synthesising these derivatives involved the diazotisation of polynitrogen compounds, especially hydrazidines such as $\mathbf{1 . 1 1}$ (Scheme 1.1), which are prepared primarily from imino ethers (imidates) and hydrazine. ${ }^{11}$

Scheme 1.1: Synthesis of 5-phenyl-1H-tetrazole (1.12) from benzimidohydrazide.

The currently favoured approach to obtain 5-STs is to react nitrile moieties with azide groups. A reaction of this type was successfully accomplished for the first time in 1901, when 5-amino-1H-tetrazole, known as diazoguanidine at the time, was prepared from cyanamide and hydrazoic acid. ${ }^{12}$ In 1910, 1 H -tetrazole itself was synthesised by a similar reaction, which involved the cycloaddition of hydrazoic acid to hydrogen cyanide. ${ }^{13}$ Hydrazoic acid, a toxic and explosive gas, was prepared either in advance or in situ and was used as a major reactant for 5-ST formation until the end of the 1950s. ${ }^{14}$

In 1958, Finnegan et al. published their fundamental work utilising sodium azide and ammonium chloride in $\mathrm{N}, \mathrm{N}$-dimethylformamide (DMF) in the synthesis of 5-STs (Scheme 1.2). Although hydrazoic acid could also be detected in the reaction mixture, this method completely changed the synthetic approaches to 5-STs. Since then, the process has become much safer, reaction times significantly reduced, and the yields of 5-STs have increased. Used to this day for the preparation of 5-STs, it has completely displaced the processes utilising hydrazoic acid. ${ }^{15}$ Many new methods and modifications of existing processes have appeared since Finnegans's methodology. The main principle in all of these methodologies
is the reaction between a nitrile and an azide moiety. These reactions can be divided into three groups: a) using acidic media, b) using Lewis acids and c) using organometallic and organosilicon azides. There is no clear distinction between these approaches and many of the latest methods combine their advantages.

Scheme 1.2: Finnegan's method for the preparation of 5-STs. ${ }^{15}$

The general disadvantage in preparing 5 -STs is the long reaction times required. Microwave (MW) irradiation has been widely explored in attempts to overcome this limitation, and has been the subject of intense investigations as a technique, with around 4000 papers been published up to $2012 .{ }^{16}$ The benefits of microwave irradiation have been suggested to be the results of thermal effects and so-called "specific microwave effects". It is of note, however, that the precise mechanism by which microwave irradiation works in organic reactions remains a contentious issue, with recent high profile publications conflicting with each other. ${ }^{17}$

### 1.1.2.1 Methods using Acidic Media (Proton Catalysed)

The methods discussed above utilising hydrazoic acid and Finnegan's method also falls into this class. Several modifications have followed, including microwave-assisted preparation of 5-STs which reduced reaction times significantly whilst retaining high yields. ${ }^{18}$ Koguro et al. carried out significant modifications to Finnegan's method by reacting sodium azide and triethylammonium chloride in toluene (Scheme 1.3). ${ }^{19}$ This process was advantageous, as the product could be easily isolated by submerging the reaction mixture into water or alkaline aqueous solution. This methodology was further improved through the use of microwave irradiation. ${ }^{20}$

Scheme 1.3: Koguro's method for preparation of 5-STs. ${ }^{19}$

With regard to the preferred mechanism of the reactions in acidic media, the following three hypotheses have been discussed: 1) concerted dipolar [2+3] cycloaddition, 2) anionic two step [2+3] cycloaddition, and 3) activation of the nitrile by protons (via an intermediate imidoyl azide). Dimroth and Fester suggested that reactions between nitriles and hydrazoic acid proceeded through the intermediate imidoyl azides. ${ }^{13}$ However, this hypothesis was not confirmed for almost one hundred years. ${ }^{21}$ Although Finnegan's group formulated the role of acid catalysis in the preparation of 5-STs, they proposed that the principle step of the reaction was the attack of the azide anion on the nitrile carbon, followed by ring closure (hypothesis 2, Scheme 1.4). ${ }^{15}$ Several reactions with the use of hydrazoic acid and ammonium azide were performed, with better results seen in the case of the ammonium salt. This hypothesis was confirmed in work by Jursic and Zdravkovski in 1994, in which a two step $[2+3]$ cycloaddition involving nucleophilic attack of the azide ion on the carbon of the nitrile group followed by tetrazole ring closure, was shown to be the preferred mechanism. ${ }^{22}$

Scheme 1.4: Mechanism of formation of 5-STs through two step [2+3] cycloaddition.

Interestingly, only the two mechanisms corresponding to hypotheses 1 and 2 were considered, with the role of acid catalysis in these reactions not being mentioned. Contradictory data supporting the concerted dipolar [2+3] cycloaddition were presented by Poplavskii et al. ${ }^{23}$ They discovered that dimethylammonium azide is generally not ionised in DMF and undergoes the reaction as the hydrogen bonded complex $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH} . \mathrm{HN}_{3}$, and not as azide anion and dimethylammonium cation. The azide part of this complex has a structure and distribution of electron density similar to those of hydrazoic acid and organic azides. Because hydrazoic acid and organic azides are typical 1,3-dipoles in dipolar cycloaddition reactions, the authors suggested that the reaction mechanism is a concerted mechanism (Scheme 1.5). ${ }^{23}$

Scheme 1.5: Mechanism of formation of 5-STs through a concerted dipolar [2+3] cycloaddition.

At the same time, they also discovered that tetraalkylammonium azides didn't react with nitriles under certain conditions. These azides only release azide anion, which is not a 1,3dipole and cannot react by 1,3-dipolar cycloaddition. The fact that tetraalkylammonium azides do not react also rules out the anionic two-step [2+3] cycloaddition mechanism. Also, while virtually all nitriles react with ammonium azide salts at elevated temperature, organic azides only react with the most activated nitriles. ${ }^{24}$ The fact that these azide salts and organic azides are electronically very similar, yet have significantly different reactivities, demonstrates that different mechanisms from those proposed in hypotheses 1 and 2 are likely in effect. Himo et al. used quantum chemical calculations to probe the energetics of various reaction mechanisms for addition of azides to nitriles. They found that in an acidic medium, the preparation of a 5-ST actually proceeds preferentially through an imidoyl azide intermediate such as 1.13, which spontaneously cyclises to the 5-ST under the reaction conditions (Scheme 1.6). As in the case of the Pinner synthesis of imidates ${ }^{25}$ or the acid hydrolysis of nitriles, ${ }^{26}$ protonation of the nitrile increases its reactivity and susceptibility to attack by azide anions. The transition state of this process is significantly lower than those of hypotheses 1 and 2 . The ammonium cation acts as a proton transfer mediator, even in the cases where the ammonium salt is not ionised in the reaction medium, which explains why tetraalkylammonium azides would not react. In the case of proton activation by the ammonium part of the salt, the energy barrier, either ionised $\left(\mathrm{NH}_{4}{ }^{+}\right)$or not ionised $\left(\mathrm{NH}_{3}\right)$, was calculated to be $\sim 21 \mathrm{kcal} \mathrm{mol}{ }^{-1}$, whereas all other discussed mechanisms showed higher energetic barriers, with values of $35 \mathrm{kcal} \mathrm{mol}^{-1}$ for concerted dipolar [2+3] cycloaddition, $34 \mathrm{kcal} \mathrm{mol}^{-1}$ for anionic [2+3] cycloaddition and $31 \mathrm{kcal} \mathrm{mol}^{-1}$ for reaction with hydrazoic acid (six-membered transition state). ${ }^{21}$ The role of the partial charge on the nitrile carbon is essential. The presence of electronwithdrawing substituents on the nitrile decreases the activation barrier and increases the reactivity of the nitrile towards azide anions. In the cases of the strongest electron acceptors, the energies of the transition states of anionic [2+3] cycloaddition are close to the energies of the ammonium-activated transition states, which is why the anionic
mechanism cannot be completely rejected. Moreover, the most electron-poor nitriles react with sodium azide without any additional reactants under very mild conditions. ${ }^{27}$

Scheme 1.6: Mechanism of formation of 5-STs via imidoyl azide intermediate 1.13.

Methods using acidic media are widely used both in small laboratories and on an industrial scale. ${ }^{16}$ The main drawbacks are the presence of highly toxic and explosive hydrazoic acid in the reaction mixtures. Merck Frosst scientists have recently addressed this issue with successful results. Reaction of a nitrile with sodium azide in the presence of catalytic zinc oxide in aqueous THF proceeded efficiently, and most notably, with only 2 ppm of hydrazoic acid in the reaction vessel headspace as measured by online IR spectroscopy. ${ }^{28}$ This modification ensured the safety of the reaction as the pH increased from 5 to 8 .

### 1.1.2.2 Methods Using Lewis Acids

Lewis acids in 5 -ST synthesis works by coordinating to nitriles and activating them towards attack by the azide anion, hence in principle, it is a similar method to the acidic media method. After some disappointing but promising results employing aluminium azide and borontrifluoride as Lewis acids in order to synthesise 5-STs, interest in this type of synthesis was regenerated in 1993. Huff et al. utilised trimethylaluminium in the synthesis of a series of 5-STs under relatively mild reaction conditions. ${ }^{29}$ In these reactions, trimethylsilyl azide $\left(\mathrm{TMSN}_{3}\right)$ served as the azide donor (Scheme 1.7).

Scheme 1.7: Preparation of 5-STs utilising trimethylaluminium. ${ }^{29}$

The main drawback for these reactions is their water sensitivity, leading to stringent reaction conditions. A major breakthrough in this field came with the publication of work by Sharpless. ${ }^{30}$ This method consisted of treatment of a nitrile with sodium azide and zinc bromide in $\mathrm{H}_{2} \mathrm{O}$ (Scheme 1.8) and enabled a more environmentally friendly route to 5-STs. Isolation of the product was easily achieved by acidification of the reaction mixture and filtration of the precipitated product. However, this method required the use of high pressure and temperatures of $170{ }^{\circ} \mathrm{C}$ for conversion of less reactive nitriles. In 2009, a solvent free method was developed from Sharpless' method which reduced reaction times but larger amounts of azide and zinc salts were required. ${ }^{31}$ Microwave assisted methods have also been developed based on Sharpless' work with the result of decreasing reaction times. ${ }^{32}$

Scheme 1.8: Sharpless' method for preparation of 5-STs. ${ }^{30}$

As in the case of the acid-catalysed synthesis, the mechanism of this type of 5-ST preparation involved a decrease in activation energy when the nitrile was coordinated to a Lewis acid. Activation energies remained unaffected when a Lewis acid was bonded to the azide ion. Activation energies for reactions where the zinc ions were only bonded to azide anions were calculated to be 34 and $36 \mathrm{kcal} \mathrm{mol}^{-1}$ for tetrahedral and octahedral coordination of zinc ions, respectively. In comparison, the activation energies of the uncatalysed reactions were $32 \mathrm{kcal} \mathrm{mol}^{-1}$ for the reaction with methyl azide and 34 kcal $\mathrm{mol}^{-1}$ with azide anions. When the zinc cation was bonded to either a nitrile or both azide and nitrile, the activation energies decreased to $25-30 \mathrm{kcal} \mathrm{mol}^{-1}$, again depending on the numbers and types of ligands. This study confirmed that the Lewis acid coordinates with the nitrile nitrogen. This coordination increases the polarisation of the nitrile moiety and decreases the activation energy of the entire reaction. ${ }^{33}$

### 1.1.2.3 Methods Using Organometallic and Organosilicon Azides

A notable class of azide donors are that of trialkyltin azides, usually in the form of trimethyltin azide or tri(n-butyl)tin azide. ${ }^{34}$ Reactions between these tin reactants and nitriles produced 5-STs in high yields, even from sterically hindered and electron rich nitriles. Molloy and co-workers also obtained 5-STs employing organotin azides without
the use of solvent. ${ }^{35}$ The main drawbacks, however, were the use of toxic reagents in high amounts. In an effort to avoid the use of toxic and volatile trialkyltin chlorides and to decrease the amount of organotin reagents necessary whilst maintaining their advantages, a 5 -ST synthesis based on trimethylsilyl azide $\left(\mathrm{TMSN}_{3}\right)$ in the presence of catalytic amounts of dibutyltin oxide $\left(\mathrm{Bu}_{2} \mathrm{SnO}\right)$ was developed. ${ }^{36}$ The reaction proceeds in a stepwise manner: the nitrile nitrogen binds to the acidic tin atom, which activates the nitrile carbon towards attack of the azide group. The open-chain intermediate then cyclises to the 1 -[dimethyl(trimethylsilyloxy)stannyl]-5-ST (1.17, Scheme 1.9). The catalytic complex $\mathbf{1 . 1 5}$ is then regenerated through a simple $S_{N} 2$ reaction between $\mathbf{1 . 1 7}$ and $\mathrm{TMSN}_{3}$ via transition state 1.18. Recently, recovery of the catalyst $\mathbf{1 . 1 5}$ from complex
1.17 has been demonstrated by treatment with azide anions. This meant that only catalytic amounts of $\mathrm{TMSN}_{3}$ and $\mathrm{Bu}_{2} \mathrm{SnO}$ together with stoichiometric amounts of inexpensive sodium azide could be used in this new protocol. ${ }^{37}$

Scheme 1.9: Mechanism for reaction between nitrile and $\mathrm{TMSN}_{3}$ in the presence of dibutyltin oxide. ${ }^{36}$

The most universal method from this group, providing high yields of 5-STs under mild conditions, was published in 2007. Dialkylaluminium azides were the crucial reactants for this procedure and the main source of azide anions, and were prepared in situ from the dialkylaluminium chlorides and sodium azide (Scheme 1.10). Their structures combine several advantages: high solubility in organic solvents, a suitable azide donor and typical Lewis acids. ${ }^{38}$

Scheme 1.10: Synthesis of 5-STs by use of dialkylaluminium azides. ${ }^{38}$

Despite the success of these group of reactions, the use of highly toxic organometallic reactants, the residues of which are often present in products meaning necessary careful separation is required, is a major drawback of these procedures.

### 1.1.3 Functionalisation of 5-Substituted Tetrazoles

5-STs are important intermediates in the synthesis of more complex compounds. Substitution of 5-STs is the most common and effective method for the preparation of 1,5and 2,5-disubstituted tetrazoles. As well as a wide range of alkyl substituents, aryl, acyl, silyl, vinyl, sulfonyl, phosphoryl and other similar groups can be introduced onto the tetrazole ring. ${ }^{39}$ The main problem with 5-ST substitution is its low and hard to control regioselectivity. Tetrazoles exist as tautomeric 1 H - and 2 H -tetrazoles (Figure 1.4), and in the presence of base they exist as the corresponding anions, where alkylation can occur at either the $\mathrm{N}-1$ or $\mathrm{N}-2$ positions.

Figure 1.4: Tautomeric forms of tetrazole. The numbering presented will be used in all other cases throughout this thesis unless otherwise stated.
$2 H$-tautomers are thought to be more stable than $1 H$-tautomers. In the crystalline state however, the majority of 5-STs exist in the $1 H$-form and are stabilised by hydrogen bonds to neighbouring molecules which results in dimers and larger agglomerates. In media that have high dielectric constants, 1 H -tautomers are preferred due to their higher polarities. A ${ }^{15} \mathrm{~N}$ NMR study of tetrazole in $d_{6}$ - DMSO revealed that $90-99 \%$ of tetrazole exists in the 1 H form. ${ }^{40}$ However, there are several situations in which the relative proportions of the 2 H tautomers strongly increase. This is seen especially in solvents with low polarity, in which the less polar $2 H$-form is better solvated. The presence of an electron-withdrawing
substituent at the 5 -position increases the polarity of the 2 H -tautomer and also the relative proportion of the 2 H -form in polar solvents. In addition, the presence of a bulky substituent in the 5-position or in the ortho-position of the phenyl ring in a 5-aryltetrazole can increase the relative proportion of the 2 H -form. ${ }^{41}$

Alkylation of a tetrazolate anion, either with or without a substituent in the 5-position almost always leads to a mixture of both 1- and 2-alkyltetrazole isomers in various ratios. The ratio of isomers formed during the reaction depends on the reaction temperature and the properties of the substituent at the 5-position. Higher reaction temperatures leads to increased amounts of 1-isomers, whereas electron-accepting properties of substituents at the 5 -position increases the amount of 2 -isomers produced. Bulky substituents direct substitution to the 2-position of the tetrazole ring. ${ }^{16}$ In the next section, several methods of alkylating a tetrazole will be discussed and the regioselectivity of the reactions will be addressed.

### 1.1.3.1 Alkylation of 5-STs

There are many methods of simple alkylation using a base such as triethylamine $\left(E t_{3} N\right)$, sodium hydroxide $(\mathrm{NaOH})$ and potassium carbonate $\left(\mathrm{K}_{2} \mathrm{CO}_{3}\right)$ in an appropriate solvent to yield the desired alkylated products. Tritylation of a $5-\mathrm{ST}$ is one of the most valuable substitutions on the tetrazole ring. The triphenylmethyl group is a fundamental protecting group of 5-STs and is used in the synthesis of more complex structures such as Losartan and its analogues. ${ }^{42}$ Alkylation of 5-STs with triphenylmethyl chloride resulted in the formation of only the 2 -isomers regardless of the substituents at the 5 -position (Scheme 1.11). ${ }^{43,44}$ This observation was not surprising, considering the size of the triphenylmethyl moiety. However, even in the case of an unsubstituted tetrazole the same observation was made. ${ }^{43}$ Tritylation most probably involves a $\mathrm{S}_{\mathrm{N}} 1$ reaction, therefore the rate limiting step is the ionisation of triphenylmethyl chloride to its respective cation. The more stable the carbocation, the higher its selectivity towards one of the two competing nucleophilic centres will be. ${ }^{45}$ This is most likely the reason high regioselectivity is seen even in the case of unsubstituted tetrazole. ${ }^{46}$

Scheme 1.11: Tritylation of 5-STs under phase-transfer catalysis conditions. ${ }^{43}$

Another highly regioselective reaction occurs in strongly acidic media. Reactions between 5-STs and secondary or tertiary aliphatic alcohols or alkenes in sulfuric acid exclusively produced 2-alkylated products. ${ }^{47,48}$ A possible explanation for this is that although 5-STs are weak bases, they are protonated in strong mineral acid solutions. The nitrogen at the 4-position is protonated preferentially, resulting in a $1 \mathrm{H}, 4 \mathrm{H}$-tetrazolium cation of type 1.19 (Scheme 1.12). The electrophilic attack of a carbocation formed from alcohol or olefin could be directed only to the $\mathrm{N}-2$ or $\mathrm{N}-3$ of the tetrazolium cation, leading exclusively to 2,5-disubstituted tetrazoles (1.21). Although an unusual interaction between two cations, MNDO quantum chemical calculations showed a high electron density localised on nitrogen atoms $\mathrm{N}-2$ and $\mathrm{N}-3$. Moreover, decreasing the acidity of the reaction medium led to an increased yield of the 1 -isomer, which is in agreement with the proposed mechanism. ${ }^{48}$

Scheme 1.12: Mechanism of 5-ST alkylation in strongly acidic media. ${ }^{47}$

In 2007, reactions of 5-phenyl- $1 H$-tetrazole and $1 H$-tetrazole potassium salts with $2,3,4,6-$ tetra- $O$-acetyl- $\alpha$-d-glucopyranosyl bromide (1.22) and methyl 2,3,6-tri-O-benzyl-4-O-triflyl- $\alpha$-D-glucopyranoside (1.23) in boiling acetone were performed (Scheme 1.13). ${ }^{49}$ During the reaction of 5-phenyl- $1 H$-tetrazole and 1.22, a mixture of both 1- and 2-isomers were formed. This was in contrast to the reaction with 1.23 which yielded only the 2isomer. In the first example, 5-phenyl-1H-tetrazole could approach a more accessible equatorial site, facilitating the formation of both isomers. In the second case, 5-phenyl- 1 H tetrazole had to approach a sterically inconvenient axial site, which allowed the formation of only the 2 -isomer (Scheme 1.14). It is worthy to note that microwave irradiation on alkylation reactions proceeded with the same regioselectivity, however did increase reaction rates.

Scheme 1.13: Reactions between potassium salts of 5-STs and glucose derivatives under microwave irradiation. ${ }^{49}$

Scheme 1.14: Sterically controlled formation of a 2,5 -disubstituted tetrazole.

### 1.1.3.2 Arylation of 5-STs

Arylations of 5-STs are described less frequently in the literature than alkylations. An example of this reaction is shown in Scheme 1.15. The reaction of sodium 5-methylsulfanyl- 1 H -tetrazolate and 4-nitrofluorobenzene resulted in the formation of both isomers in a 1:3 ratio. 5 -aryltetrazoles did not react under these conditions, however the employment of 2,4-dinitrofluorobenzene resulted in successful reactions with these derivatives under mild conditions. ${ }^{50}$

Scheme 1.15: Arylation of 5-STs with 2,4-dinitrofluorobenzene 1.25.50

Microwave-assisted arylations of 5 -STs by treatment of their sodium salts with 4nitrofluorobenzene in DMSO have recently been described (Scheme 1.16). With 5-aryl-1 H tetrazoles the reactions led regioselectively to the formation of 2,5-diaryl- 2 H -tetrazoles. In the cases of more compact substituents such as 5 -alkyl-1H-tetrazoles however, the reactions yielded mixtures of both regioisomers. ${ }^{51}$

Scheme 1.16: Arylation of 5-STs with 4-nitrofluorobenzene under microwave irradiation conditions. ${ }^{51}$

### 1.1.3.3 Vinylation of 5-STs

The vinylation of tetrazoles is an interesting concept due to the possibility of subsequent reaction of the vinyl product to form further heterocyclic derivatised tetrazoles. Although several methods for the preparation of 5 -substituted 2 -vinyl- 2 H -tetrazoles have been published, all have substantial disadvantages. The first direct vinylation methods used mercuric acetate, a toxic mercuric salt, which resulted in low yields. Analogous reactions with palladium(0) catalysts led to low yields with a high tendency to polymerise. ${ }^{52}$

Roh et al. recently developed a one-pot regiospecific synthesis of 5 -substituted-2-vinyl2 H -tetrazoles through a simple procedure without a metal catalyst or organocatalyst. The group found that the reaction of 5-phenyl-1 H -tetrazole with 1,2-dibromoethane and $\mathrm{Et}_{3} \mathrm{~N}$ in a 1:1:2 molar ratio in MeCN led to the preferential formation of 5-phenyl-2-vinyl-2Htetrazole. By increasing the ratio of dibromoethane and $\mathrm{Et}_{3} \mathrm{~N}$ the yield of the vinyl product was seen to rise from $60-80 \%$, while decreasing the amount of dimers formed. The mechanism of the reaction was investigated in order to explain the regiospecificity of the
reaction. They proposed that the $\mathrm{Et}_{3} \mathrm{~N}$ reacted with 1,2-dibromoethane to form (2bromoethyl)triethylammonium bromide (1.26, Scheme 1.17) which reacted with the tetrazole producing 1.27. Substitution at the 2-position of the tetrazole rings is probably directed by the steric requirements of $\mathbf{1 . 2 7}$. Under these reaction conditions, $\mathbf{1 . 2 7}$ could undergo spontaneous elimination to produce a vinyl derivative. ${ }^{53}$

Scheme 1.17: Mechanism of regioselective vinylation. ${ }^{53}$

### 1.2 Coordination Chemistry - Overview Of Topics Relevant to Thesis

In this section, a brief account of one of the most important bonding theories that rationalise experimental facts such as electronic spectra and magnetic properties of coordination compounds is discussed. The discussion will focus on first row d-block metals, for which this theory of bonding is most successful. The phenomenon of Jahn-Teller distortions will also be discussed.

### 1.2.1 Crystal Field Theory

Crystal field theory is an electrostatic model which focuses on the interaction of donor electrons from ligands and the metal centre. Each ligand is treated as a point charge and there is an electrostatic interaction between the metal ion and the ligands. However there is also a repulsive interaction between electrons in the d orbitals and the ligand point charges. Of the five d orbitals, three have their lobes directed in between the $x, y$ and $z$ axes, while the other two are directed along these axes (Figure 1.5). As a consequence of this difference, the d orbitals in the presence of ligands are split into groups of different energies. The type of splitting and the magnitude of the energy differences between the
orbitals depend on the arrangement and the nature of the ligands. Magnetic properties and electronic spectra, both of which are observable properties, reflect the splitting of the d orbitals and hence these techniques can yield useful information about the electronic structure of coordination compounds.

Figure 1.5: Representation of the five d orbitals on a Cartesian axis.

Crystal field theory can be conveniently illustrated by considering a first row metal cation surrounded by six ligands placed on a Cartesion axes at the vertices of an octahedron. If the electrostatic field was spherical, then the energies of the five 3d orbitals would be destabilised by the same amount. However, since the $\mathrm{d}_{z}{ }^{2}$ and $\mathrm{d}_{x}{ }^{2}-y^{2}$ atomic orbitals point directly at the ligands and the $\mathrm{d}_{x y}, \mathrm{~d}_{y z}$ and $\mathrm{d}_{x z}$ atomic orbitals point between them, the $\mathrm{d}_{z}{ }^{2}$ and $\mathrm{d}_{x^{2}-y^{2}}$ atomic orbitals are destabilized to a greater extent than the $\mathrm{d}_{x y}, \mathrm{~d}_{y z}$ and $\mathrm{d}_{x z}$ atomic orbitals (Figure 1.6).

Figure 1.6: Splitting of the d orbitals in an octahedral crystal field.

The energy separation between the energy levels is $\Delta_{\text {oct }}$. The magnitude of $\Delta_{\text {oct }}$ is determined by the strength of the crystal field. $\Delta_{\text {oct }}$ for a weak crystal field is smaller than for a strong crystal field. Factors governing the magnitude of $\Delta_{\text {oct }}$ are the identity and oxidation state of the metal ion and the nature of the ligands. For octahedral complexes, $\Delta_{\text {oct }}$ increases along the spectrochemical series of ligands (seen below), with ambidentate ions appearing in two positions in the series.

$$
\mathrm{I}^{-}<\mathrm{Br}^{-}<[\mathrm{NCS}]^{-}<\mathrm{Cl}^{-}<\mathrm{F}^{-}<[\mathrm{OH}]^{-}<\mathrm{H}_{2} \mathrm{O}<[\underline{\mathrm{NCS}}]^{-}<\mathrm{NH}_{3}<\text { en }<\text { bipy }<\text { phen }<[\mathrm{CN}]^{-}
$$

For $\mathrm{d}^{1}, \mathrm{~d}^{2}$ and $\mathrm{d}^{3}$ metal ions in an octahedral crystal field, the electrons fill the d orbitals according to Hund's rule and hence will occupy each of the three degenerate orbitals that possess $t_{2 g}$ symmetry. For a d ${ }^{4}$ ion, two arrangements are possible: the four electrons may occupy the $t_{2 g}$ set or may singly occupy four d orbitals (Figure 1.7). Configuration A corresponds to a low-spin arrangement and $B$ to a high-spin arrangement. The preferred configuration is that with the lower energy and depends on whether it is energetically favourable to pair the fourth electron or promote it to the $e_{g}$ level. The energy required to pair two electrons in the same orbital is termed the pairing energy, P. For high spin metal complexes $\Delta_{\text {oct }}$ must be less than P, and for low spin metal complexes $\Delta_{\text {oct }}$ must be greater than P. Therefore, a correlation can be established between types of ligand (strong or weak field ligands) and preferences for high- or low-spin complexes.

Figure 1.7: A low-spin (A) and high-spin (B) arrangement of electrons for a $d^{4}$ ion in an octahedral crystal field.

### 1.2.2 Jahn-Teller Distortions

In 1937, Hermann Jahn and Edward Teller published their theory which stated that any non-linear system in a degenerate energy state will be unstable and will undergo distortion to form a system of lower symmetry and lower energy, thereby removing degeneracy. ${ }^{54}$ These Jahn-Teller distortions are most often associated with transition metal centres. In a ligand field, the splitting of the d orbitals of a metal ion can often lead to degenerate electron configurations that are subject to Jahn-Teller effects. For example, octahedral symmetry $\mathrm{d}^{1}, \mathrm{~d}^{2}, \mathrm{~d}^{4}$ (both spin-states), $\mathrm{d}^{5}$ (low-spin), $\mathrm{d}^{6}$ (high-spin), $\mathrm{d}^{7}$ (both spin-states) and $d^{9}$ transition ions all have an orbitally degenerate electron configuration that should be Jahn-Teller active. Ions with degenerate occupancy of the $e_{g}$ subshell nearly always exhibit strong Jahn-Teller distortions, because of the M-L antibonding character of these orbitals. ${ }^{55}$ Therefore, the Jahn-Teller effect is pronounced in six-coordinate complexes of high-spin $\mathrm{d}^{4}$, low-spin $\mathrm{d}^{7}$ and $\mathrm{d}^{9}$ ions, with six-coordinate $\mathrm{Cu}(\mathrm{II})$ compounds being the most common Jahn-Teller distorted systems. For Cu (II) in an octahedral environment, Jahn-Teller distortions will have the effect of elongating either the two axial metal-ligand bonds or the four equatorial metal-ligand bonds. This is due to one of the $e_{g}$ atomic orbitals containing an unpaired electron and the other being doubly occupied. If the doubly occupied orbital is in the $\mathrm{d}_{z}{ }^{2}$ orbital, most of the electron density in this orbital will be concentrated between the cation and the two ligands on the $z$ axis. Thus there will be greater electrostatic repulsion associated with these ligands than with the other four and the complex is axially elongated. Conversely, occupation of the $\mathrm{d}_{x^{2}-y^{2}}$ orbital would lead to elongation along the $x$ and $y$ axes. ${ }^{56}$ Both distortions lower the energies of two electrons in the $e_{g}$ subshell, while raising the energy of only one, yielding a net reduction in electronic energy upon distortion of the complex (Figure 1.8).

Figure 1.8: The two distortions of an octahedral $\mathrm{Cu}(\mathrm{II})$ complex. ${ }^{55}$

### 1.3 Metals in Anti-Cancer Agents

The origin of research in employing metal compounds against various tumour diseases can be attributed to the serendipitous discovery of the anti-neoplastic properties of cisplatin by Barnett Rosenberg. ${ }^{57}$ The clinical use of this drug has been restricted due to dose-dependent side effects and resistance, coupled with a narrow spectrum of activity. This has been somewhat amended by the development of carboplatin and oxaliplatin (Figure 1.9). These metal complexes are used in about $50 \%$ of all tumour therapies and display remarkable therapeutic activity in a series of solid tumours. ${ }^{58}$

(a)

(b)

(c)

Figure 1.9: Structures of (a) cisplatin; (b) carboplatin and (c) oxaliplatin.

However, these remain to have similar drawbacks to those of cisplatin. The non-desirable effects of cisplatin and its derivatives have had the result of stigmatising the use of metalbased drugs in chemotherapy. In recent years however, this view has lapsed as indicated by the increase in the number of publications in this area. This is because medicinal inorganic chemistry has been realised as a field that offers additional opportunities for the
design of therapeutic agents that are not accessible to organic compounds. The wide range of coordination numbers and geometries, available redox states, thermodynamic and kinetic characteristics and intrinsic properties of the metal cation and ligand itself offer a large variety of reactivities to be exploited compared to conventional carbon-based compounds. Therefore an extensive search into alternative strategies, based on different metals with improved pharmacological properties and an extended spectrum of activity, has been undertaken. Metal complexes containing zinc, copper, gold and ruthenium have received considerable attention as potential anti-cancer agents. ${ }^{59,60}$ Furthermore, the investigation of ruthenium containing compounds in clinical trials attests to the rich potential of utilising non-platinum metal-based compounds in the treatment of cancer. ${ }^{61}$ Copper complexes as anti-cancer agents is a rapidly expanding area of research as illustrated by the increasing number of publications reported since 2000 (Figure 1.10). In $\mathrm{Cu}(\mathrm{II})$ complexes, the coordination number varies from four to six allowing different geometries to exist. This variety of arrays allows for an assortment in the choice of ligands and donor atoms. This increase in popularity can also be seen with other d-block metals.

Figure 1.10: Number of articles in Web of Science on the topic "copper and anti-cancer" from 2000 to $2013 .{ }^{62}$

The breadth of this area is far too large to satisfactorily cover in this report, however extensive reviews in the literature more than adequately do this area justice and illustrate that the potential of this strategy should not be underestimated. ${ }^{60,63}$ As the focus of this thesis is on N -donor systems, a number of relevant examples are shown in Figure 1.11. A brief overview of tetrazole metal complexes and their anti-cancer activites will be undertaken in Chapter 2.

Figure 1.11: A selection of 'non-classical' anti-cancer agents which have shown promising anti-cancer activities. ${ }^{64}$

### 1.4 Metal-Organic Frameworks

Metal-Organic Frameworks (MOFs) (also known as coordination polymers) are crystalline coordination networks consisting of metal ions/clusters and organic linkers joined in a 1 , 2 or 3D fashion. ${ }^{65,66}$ A rapidly expanding field in chemical and materials sciences, MOFs display fascinating topologies and exploitable properties for potential applications such as gas adsorption and separation, ${ }^{67}$ catalysis, 68 luminescence, 69 sensing, 70 proton conduction, ${ }^{71}$ tunable magnetism, ${ }^{72}$ explosives, ${ }^{73}$ and drug delivery. ${ }^{74}$ As well as these appealing aspects of MOFs, their potential scalability to industrial scale have made these materials an attractive target for further study.

### 1.4.1 Historical Developments and Nomenclature

The relatively young field of MOF synthesis evolved from its foundations in the fields of coordination, materials and zeolite chemistry. In 1989 and 1990, Hoskins' and Robson's seminal work set the basis for the future of MOFs. 75,76 They envisioned the formation of a large range of crystalline, microporous, stable solids, with ion exchange, gas sorption or catalytic properties that further allowed the introduction of functional groups by postsynthetic modification. This vision has subsequently been demonstrated by many scientists and the range of structures continues to expand at an unprecedented rate with more than 20,000 MOF structures reported and studied since the early 1990s. ${ }^{66}$ The term MOF was made popular around 1995 by Yaghi et al. ${ }^{77}$ a prolific author in the area. In the
following years, their potential applications became fully realised with the work by Kitagawa et al., ${ }^{78}$ who synthesised a porous 3-D MOF that exhibited gas sorption properties at room temperature; Yaghi et al. ${ }^{79}$ and Williams et al. ${ }^{80}$ who reported the syntheses of MOF-5 and HKUST-1 respectively and set the benchmark in MOF chemistry with their high porosities (Figure 1.12); and Férey et al. ${ }^{81}$ who synthesised non-flexible and flexible porous MOFs. Thereafter, MOFs soon became established as better absorbant materials than conventional porous materials such as zeolites, carbons and silicas. Furthermore, it became clear that with judicious choice of metal ions or secondary building units (SBUs, polyatomic clusters) and linkers, the idea of controlling and designing the frameworks obtained was a real possibility, yielding opportunities to modify pore sizes, shapes and functionalities. In reality, the 'design' of MOFs requires a high degree of predictability to be integrated into the synthesis which is especially hard to realise when extending it to more complicated cases, not to mention consideration of other variables such as temperature, solvent and concentration which also affect product crystallinity and morphology. Nonetheless, the prospect of 'solids by design' has attracted the interests of scientists in both academia and industry.

Figure 1.12: Structures of the first porous MOFs (a) a 4,4'-bipyridine linked 3-D porous MOF synthesised by Kitagawa et al.;78 (b) MOF-579 and (c) HKUST-1.80

With origins in solid state, inorganic and coordination chemistry, the diversity in the focus and the scientific base of those involved in MOF chemistry has led to the use of a variety of terminologies for this class of compounds. Moreover, the nomenclature used is not consistent among research groups and much discussion has taken place regarding the
most correct terminology. ${ }^{82}$ A IUPAC task group was given the responsibility to produce terminology and nomenclature guidelines for coordination polymers (CPs) and MOFs and their final recommendations were published in 2013.83 Their conclusions were that the term coordination polymer is the collective term for coordination networks and MOFs since by definition they have "repeating coordination entities extending in 1-, 2- or 3dimensions". They defined a coordination network as a "coordination compound extending through repeating coordination entities in 1-dimension but with cross-links between two or more individual chains, loops or spiro-links, or a coordination compound extending through repeating coordination entities in 2- or 3- dimensions". They further define MOFs as "coordination networks with organic ligands containing potential voids", with proof of porosity not necessary. Although tasked with the responsibility of setting out guidelines, this report has led to further disputes amongst scientists in this area of chemistry. ${ }^{84}$ Despite these disagreements, this thesis will attempt to adhere to these IUPAC recommendations throughout.

### 1.4.2 Synthesis of Coordination Polymers

Synthesis of CPs involves the use of organic ligands and metal ions or clusters. A plethora of different synthesis methods have been applied over the last 20 years to obtain CPs (Figure 1.13). In addition to room temperature synthesis, conventional electric heating (CE), microwave heating (MW), electrochemistry (EC), mechanochemistry (MC) and ultrasonic (US) methods have been employed. The term conventional synthesis is applied to reactions carried out by conventional electric heating. The reaction temperature is one of the main parameters in the synthesis of CPs and two temperature ranges, solvothermal and nonsolvothermal are normally distinguished which dictate the kind of reaction setups that have to be used. A common definition of solvothermal are those taking place in closed vessels under autogenous pressure above the boiling point of the solvent. Accordingly, nonsolvothermal techniques are those that take place below or at the boiling point of the solvent under ambient pressure. These methods also involve the slow evaporation of the reaction solvent. These methods are well known to grow crystalline solids, as it is possible to tune the reaction conditions, i.e. the rate of nucleation and crystal growth. Methods such as solvent evaporation of a solution of reactants, layering of solutions, or slow diffusion of reactants into each other lead to concentration gradients that allow the formation of CPs. Concentration gradients can also be accomplished using temperature as a variable, i.e. by applying a temperature gradient or slow cooling of the reaction mixture. Alternative synthetic routes have also been developed where the reaction has a different energy
source than a conventional hotplate or oven. The development of these other methods is important as different methods can lead to new compounds which cannot be obtained otherwise. Furthermore, different methods can lead to different particle sizes and morphologies that can have an influence on the material's properties. For example, different particle sizes in porous materials can influence the diffusion of guest molecules, which have a direct impact on catalytic reactions or the absorption and separation of molecules. Small crystals may also be employed for the formation of membranes using a seeded growth procedure. Nanocrystalline, non-toxic MOFs with high loading capacities are also envisioned for biomedical applications. For these objectives, MW and US techniques have been applied. High-Throughput Methods (HT) have also been developed to allow efficient investigations into the many parameters involved in CP synthesis. ${ }^{85}$

Figure 1.13: MOF synthesis is a multi-faceted task with consideration of synthesis methods and crystal growth necessary.

### 1.4.2.1 Microwave-Assisted Synthesis

Microwave-assisted heating has mainly been used in organic chemistry, ${ }^{86}$ and only recently has been employed in inorganic chemistry and MOF synthesis. ${ }^{87}$ This change in focus has been brought about by the desire to reduce reaction times, increase yields and synthesise large amounts of functional materials, which also enhances their industrial
applicability. MW has beneficial attributes in that it allows one to monitor temperature and pressure during the reaction, thus allowing more precise control of reaction conditions. With the manipulation of the size and shape of the crystals becoming an emerging area of MOF research, ${ }^{88}$ MW has the benefit of generally producing homogenous sometimes nanoscale materials which are key for their applications in magnetic resonance imaging ${ }^{89}$ and drug delivery. ${ }^{90}$ On the other hand, working with microwaves raises some concern with respect to safety and reproducibility. Although reactions are fast and usually proceed at low temperatures, the morphology and phase purity of the products can be adversely affected if the reaction conditions are not strictly controlled, thus affecting the mechanical strength, conductivity and chemical reactivity of the products. Different instruments are also unable to deliver the same conditions, ultimately hindering reproducibility.

### 1.4.2.2 Electrochemical Synthesis

Electrochemical synthesis of MOFs was first reported by BASF researchers in 2005. ${ }^{91}$ The objective of this work was to negate the use of metal salts which are commonly used in MOF synthesis, as anions like nitrate, perchlorate and chloride are of concern to largescale production processes. Instead of using metal salts, the metal ions are continuously introduced by aniodic dissolution to the reaction medium which contains the dissolved linker and a conducting salt. The isolation of the product is then achieved via a simple filtration. The pioneering work by BASF resulted in the attainment of four $\mathrm{Cu}-\mathrm{or} \mathrm{Zn}$ containing compounds with high porosity, one of which was the well-studied HKUST-1 (Figure 1.14) which was tested for its use in gas purification (i.e. removal of tetrahydrothiophene from natural gas) and $\mathrm{H}_{2}$ storage. ${ }^{92}$ In a comparative study on the influence of the synthesis procedure on the properties of HKUST-1, the compound was synthesised by solvothermal, ambient pressure and electrochemical routes in pure EtOH and EtOH $/ \mathrm{H}_{2} \mathrm{O}$ mixtures. ${ }^{93}$ In all cases HKUST-1 was formed, however thermogravimetric analysis (TGA), elemental analysis and sorption experiments showed an inferior quality of the electrochemically synthesised product. This was explained by the incorporation of linker molecules and/or the conducting salt in the pores during crystallisation.

Figure 1.14: Structure of HKUST-1. Oxygen = red, copper = blue, carbon = grey.

### 1.4.2.3 Mechanochemical Synthesis

The interest in mechanochemical MOF synthesis is due to multiple reasons. One important reason is environmental issues. Reactions can be carried out at room temperature in solvent free conditions which is especially desirable when organic solvents are avoided. Quantitative yields can be obtained in short reaction times (in the range of 10-60 min) and products consisting of small particles are obtained. Another advantage of this technique is the use of metal oxides as starting materials which results in the formation of water as the only side product. The use of mechanochemistry for the synthesis of porous MOFs was first reported in 2006.94 The mechanochemical synthesis of HKUST-1 was studied in detail. ${ }^{93,95}$ Starting from a stoichiometric ratio of $\mathrm{Cu}^{2+}$ to benzene-1,3,5-tricarboxylic acid ( $\mathrm{H}_{3} \mathrm{BTC}$ ) (3:2), solvent free grinding as well as liquid-assisted grinding (LAG) resulted in the desired product. Cu salts, grinding conditions (time and frequency), presence/absence of solvent, and nature of the solvent (DMF, $\mathrm{MeOH}, \mathrm{H}_{2} \mathrm{O} / \mathrm{EtOH}$ ) were studied. Copper acetate was shown to be the starting material of choice and LAG led to better crystalline products with better sorption properties. The pores of the products contained residual reactants, acetic acid and water molecules which was proven by TGA and TG-MS measurements as well as spectroscopic methods. The guest molecules could be removed by washing followed by thermal treatment, however thermal treatment alone led to small specific surface areas.

### 1.4.2.4 Sonochemical Synthesis

Sonochemistry involves the application of ultrasonic energy to the reaction mixture. Ultrasound is a cyclic mechanical vibration with a frequency of 20 kHz to 10 kHz . No direct interaction between ultrasound and molecules occurs but areas of high pressure and low pressure are formed when high-energy ultrasound interacts with liquids. In the low
pressure regions the pressure drops below the vapour pressure of the liquid and small bubbles or cavities are formed. The bubbles formed grow under the alternating pressure through the diffusion of solute vapour into the volume of the bubble. Thus, ultrasonic energy is accumulated. Once the bubbles reach their maximum size, they become unstable and collapse. This process leads to the rapid release of energy with temperatures of $\sim 5000$ K. These 'hot spots' present unusual conditions. The extreme conditions and intense shear forces can lead to the formation of molecules in an excited state, bond breakage and the formation of radicals that will further react. ${ }^{96}$ Ultrasonic techniques were first applied to MOF synthesis in 2008 with the goal of finding a fast, energy efficient, environmentally friendly, room temperature method that could easily be carried out. In addition, nanocrystalline particles which are often obtained by sonochemical syntheses were also anticipated to be of advantage for their applications. Three studies were reported on the synthesis of HKUST-1.93,97,98 The first report investigated the influence of reaction time starting from copper acetate and $\mathrm{H}_{3} \mathrm{BTC}$ in a mixed solution of $\mathrm{DMF} / \mathrm{EtOH} / \mathrm{H}_{2} \mathrm{O} .{ }^{97}$ Using an ultrasonic bath and varying reaction time, the desired product was obtained after 5 min as a nanocrystalline powder. Increasing the reaction time led to larger crystals and higher yields. Using the same starting materials and the three solvents, the amount of DMF was increased stepwise and the reaction time was varied. In contrast to conventional and MWassisted heating, DMF was necessary for the formation of HKUST-1. After 1 min , a phase pure and highly crystalline product was obtained. The concentration of DMF was found to have a strong influence on the physical properties of the product. ${ }^{98}$ In contrast to these studies, the third report concerns the successful synthesis of HKUST-1 in a mixture of EtOH and $\mathrm{H}_{2} \mathrm{O}$, while a product of poor quality was formed in pure DMF with specific surface areas smaller than optimised products. ${ }^{93}$

### 1.4.3 Post-Synthetic Modifications

There has been substantial interest in tuning the physical and chemical properties of MOFs by functionalising their pores in order to tailor and modify their host-guest interactions. This relies on the development of MOFs that possess complex chemical functionality that can impart sophisticated chemical and physical properties to these materials. Historically, incorporating functionality into a MOF was achieved by modifying an organic ligand with specific substituents and then using the modified ligand directly in the solvothermal synthesis of the desired MOF. This 'prefunctionalisation' approach has resulted in MOFs with pendant groups such as $-\mathrm{Br},-\mathrm{NH}_{2},-\mathrm{CH}_{3}$, and other relatively simple substituents lining the pore channels. However, the preparation of highly functionalised

MOFs has been largely limited by the solvothermal synthetic methods used to prepare most MOFs. Under solvothermal conditions, ligands generally cannot contain functional groups that are thermally labile, result in problematic solubility or can coordinate to metal ions. Unfortunately, many functional groups of interest fall into one or more of these categories. Therefore, the scope of functional groups within the pores of the MOFs has remained relatively limited by this approach.

Another route for obtaining functionalised MOFs is by post-synthetic modification (PSM). ${ }^{99}$ PSM, which was originally suggested by Hoskins and Robson ${ }^{75}$ in 1990 and formally introduced by Wang and Cohen, ${ }^{100}$ is defined as the chemical modification of a framework after it has been synthesised. Rather than synthesising a functionalised MOF directly from a functionalised ligand, a MOF can be synthesised and modified in a heterogeneous manner after the formation of the solid lattice. PSM can be advantageous compared to the prefunctionalisation approach for a number of reasons. Firstly, one has greater control over the types and number of functional groups that can be incorporated into the framework. Secondly, this approach circumvents any incompatibility with the synthetic methods required to obtain the material. Also, the fact that MOFs contain an organic component offers opportunities to employ a vast range of organic transformations. Finally, because MOFs are highly porous, the ability of reagents to access the interior of the solid suggests that functionalisation can be achieved on both the interior and exterior of the material, which is in contrast to many inorganic solids like nanoparticles where only the surface of the materials is available for modification. Apart from removing or absorbing guest molecules, which by themselves are a post-synthetic modification of a MOF material, PSM of MOFs can be broadly divided into three areas (Figure 1.15): covalent PSM, dative PSM and post-synthetic deprotection (PSD). Covalent PSM is defined as the use of a reagent to modify a component (usually the organic linker) of the MOF in a heterogenous manner to form a new covalent bond. This is one of the earliest reported and most examined methods. Dative PSM is defined as the use of a reagent that forms a dative (coordinative) bond with a component of the MOF in a heterogenous and post-synthetic manner. Examples include adding a ligand to the framework that coordinates to the metal in the MOF or adding a metal source which can become bound to the organic linker by dative bonds. PSD is a reaction performed on the MOF in a post-synthetic manner that results in the cleavage of a chemical bond within an intact framework. As post-synthetic modifications are not the focus of this thesis, a brief overview of successful examples of PSM will be presented.

Figure 1.15: Generic schemes for covalent PSM, dative PSM and PSD.

### 1.4.3.1 Covalent PSM

The earliest example of covalent PSM was encountered in 1999, ${ }^{101}$ when $1,3,5$-tris(4ethynylbenzonitrile)benzene derivatives, with a variety of substituents in the 2-position of the central benzene ring, were assembled with silver triflate. Among the substituted ligands employed for the study, one contained a pendant alcohol group on the 2-position (Scheme 1.18). Upon assembly of a MOF from the alcohol-derivitised ligand the MOF was exposed to vapors of trifluoroacetic anhydride, followed by quenching with benzyl alcohol to consume the excess anhydride. Conversion of the alcohol to the ester was confirmed by FTIR and ${ }^{1} \mathrm{H}$ NMR spectroscopy by dissolving the material in $d_{6}$-acetone. This first example of covalent PSM highlights the important principles and methods that are now central features in the area of PSM. These features include the use of a ligand possessing a free functional group (a 'tag'), chemical modification in a heterogenous manner, preservation of crystallinity and dissolution of the solid after modification to permit use of solution NMR spectroscopy to characterise the reaction products.

Scheme 1.18: The pendant alcohol group on the symmetrical 1,3,5-tris(4ethynylbenzonitrile)benzene ligand was not involved in MOF synthesis with silver triflate, allowing it to serve as a chemical handle for covalent PSM with trifluoroacetic anhydride. ${ }^{101}$

Despite these results and the array of possibilities that they promised, the covalent PSM approach only gained worthy attention in earnest in 2007 when Wang and Cohen, who coined the term "post-synthetic modification", described the reaction of IRMOF-3 with acetic anhydride. ${ }^{100}$ The aromatic amines in IRMOF-3 do not engage in binding to the SBUs and thereby provide the chemical handle for performing PSM. Under mild conditions at room temperature, IRMOF-3 was acetylated in $>90 \%$ yield with acetic anhydride to produce IRMOF-3-AM1 (Scheme 1.19). The degree of conversion was confirmed by ${ }^{1} \mathrm{H}$ NMR spectroscopy upon digestion of the material in $d_{6}$-DMSO and DCl. The material also remained porous, however the surface areas were greatly reduced. Several other reports of covalent PSM of amine-, azide- and aldehyde-tagged MOFs are also now prevalent in the literature. ${ }^{102}$

Scheme 1.19: PSM of IRMOF-3 with acetic anhydride. ${ }^{100}$

### 1.4.3.2 Dative PSM

Dative PSM was reported as far back as 1999,80 with the original description of HKUST-1. In this early report, the authors noted that the coordinated axial water molecules on the SBUs could be removed by heating HKUST- 1 in air to $100^{\circ} \mathrm{C}$. The resulting material could then be immersed in dry pyridine to obtain a material with pyridine molecules bound to the SBU (Scheme 1.20). Importantly, the HKUST-1 derivative could not be directly synthesised by solvothermal methods, demonstrating the importance of dative PSM. Similarly in 2008, Hupp and colleagues demonstrated that axially bound DMF molecules in a Zn (II) paddlewheel SBU could be removed under vacuum with heat (Scheme 1.20). ${ }^{103}$ The desolvated MOF could then be treated with pyridine derivatives in DCM that bound to the axial sites left vacant on the SBUs by removal of DMF. Several of the pyridine ligands introduced would decompose under solvothermal conditions demonstrating that dative PSM could be used to introduce thermally labile species into a MOF. Secondly it was shown that $\mathrm{H}_{2}$ uptake was dependent on the pyridine species coordinated to the SBUs indicating that the MOF properties could be altered by dative PSM.

Scheme 1.20: Dative PSM on the SBUs of several MOFs with pyridine derivatives. ${ }^{80,103}$

Another dative PSM approach involves using an organic ligand that contains two or more types of metal binding sites. Under judicious choice of reaction conditions, one of the metal binding groups becomes involved in the framework synthesis and coordinates to the metal
centre (forming a SBU). The other metal binding site is not involved structurally and thus is available for post metal insertion. ${ }^{102,104,105} \mathrm{~A}$ recent notable example of this type of dative PSM was reported by Yaghi and Long. ${ }^{106}$ The ligand used in this study was 2,2'-bipyridine-5,5'-dicarboxylic acid which possesses the metal-binding $2,2^{\prime}$-bipyridine core that is ubiquitous in MOF chemistry. The challenge with this ligand is that the bipy core binds metal ions so avidly that it is likely to bind metal ions during solvothermal synthesis. Based on the Hard-Soft-Acid-Base (HSAB) theory of coordination chemistry, Yaghi and Long exploited the generally soft nitrogen donors in the ligand due to its $\pi$-accepting character and the hard nature of the carboxylate oxygens by selecting a hard oxophilic metal ion to construct the framework. Employing an $\mathrm{Al}(\mathrm{III})$ salt resulted in exclusive coordination to the hard carboxylate oxygen donors during solvothermal synthesis, forming the open framework MOF-253 (Scheme 1.21). The free bipy nitrogen sites in MOF-253 were proven accessible by utilising dative PSM on the unit with softer metal ions including $\mathrm{Cu}(\mathrm{II})$ and $\mathrm{Pd}(\mathrm{II})$. Soaking MOF-253 in $\mathrm{CH}_{3} \mathrm{CN}$ solutions of $\mathrm{Cu}\left(\mathrm{BF}_{4}\right)_{2}$ or $\mathrm{PdCl}_{2}$ could produce materials where $>80 \%$ of the bipy ligands were metalated, as determined by elemental analysis.

Scheme 1.21: Post-synthetic metalation of MOF-253. ${ }^{106}$

### 1.4.3.3 Post-Synthetic Deprotection

PSD is a PSM method quickly gaining attention. PSD is based on the concept that a protected or "masked" functional group is introduced onto an organic linker and the linker is then incorporated into a MOF under standard solvothermal conditions. The
protecting group is then subsequently removed in a post-synthetic fashion to reveal the desired functionality. Telfer and colleagues clearly demonstrated the utility of PSD in 2010 by validating the ability to prevent framework interpenetration. ${ }^{107}$ Framework interpenetration can be problematic for applications like gas absorption, as interpenetrating linkers can occupy the available space. The amine tag on the ligand 2-aminobiphenyl-4,4'-dicarboxylate was protected with a bulky tert-butyloxycarbonyl (Boc) protecting group. Combination of this ligand with $\mathrm{Zn}(\mathrm{II})$ under solvothermal conditions gave an IRMOF-10 analogue showing a clear absence of framework interpenetration. The bulky tert-butyl protecting groups prevented interpenetration, which is generally a difficult feature to control in MOFs produced from extended ligands. Thermolysis of the IRMOF at $150^{\circ} \mathrm{C}$ in DMF resulted in removal of the Boc group to generate IRMOF-12-NH2 with free amine tags within the pores (Scheme 1.22). Attempts to produce this product by directly employing 2-amino-biphenyl-4,4'-dicarboxylate have not been successful.

Scheme 1.22: Thermally induced PSD on a protected IRMOF. ${ }^{107}$

The PSM approach to the modification and functionalisation of MOFs has become a vibrant area of research in the last few years. The resulting materials have been shown to engender MOFs with new properties relevant to gas sorption, catalysis and biomedical applications. This will no doubt lead to new exciting contributions to an already rapidly evolving area, which is reflected by the number of reviews published in the last five years. ${ }^{65,66,96,99,102,108}$

### 1.5 Aims of Thesis

The overall aims of this project are two pronged. Firstly this thesis aims to describe the synthesis and characterisation of pyridyl tetrazole based ligands and their respective metal complexes. This work was carried out with the long term goal of carrying the resulting compounds through to anti-cancer biological testing. The metal ions used included $\mathrm{Cu}^{2+}, \mathrm{Zn}^{2+}, \mathrm{Ni}^{2+}$ and $\mathrm{Co}^{2+}$.

This thesis also aims to describe the development and characterisation of coordination polymers based on heteroaryl carboxylate functionalised tetrazole linkers. The goal in employing these ligands in coordination polymer synthesis was to form open networks or frameworks with potential voids which would endow the materials with interesting properties for potential applications in gas storage, gas separation, chemical sensing or drug delivery. The metal ions employed in this work were $\mathrm{Cu}^{2+}, \mathrm{Zn}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Co}^{2+}$ and $\mathrm{Mn}^{2+}$.

We hoped that this work would highlight the versatility and usefulness of heteroaryl tetrazole ligands in the fields of medicinal chemistry and materials chemistry, and that it will add value to both these fields of chemistry.

## Chapter 2: Synthesis and Characterisation of Pyridyl Tetrazole Ligands and Their Metal Complexes

### 2.1 Introduction

### 2.1.1 Inorganic Complexes in Medicinal Chemistry

The importance of metal-based compounds in medicinal chemistry dates back to the $16^{\text {th }}$ century, with the first reports of their therapeutic effects in the treatment of cancer. ${ }^{109}$ Metal-containing drugs are now not just limited to anti-cancer treatments. Silver compounds for example exhibit anti-microbial activity, gold compounds demonstrate antiarthritic activity, bismuth compounds displays anti-ulcer properties and vanadium exhibits anti-diabetic activity. ${ }^{110}$ As discussed in Chapter 1, the synthetic production of tetrazoles has improved over the last decade. ${ }^{24,30}$ As a consequence, more attention has been focused on tetrazole compounds and they have become an interesting candidate in the design of new biologically active drugs and also metal-based drugs. This is due to the metal ion binding capabilities of such compounds. Thus, the study of the structures of tetrazole derivatives is relevant to several aspects of medicinal chemistry as is their coordination chemistry given the increasing importance of metal-based drugs which incorporate known therapeutic organic agents. ${ }^{111}$

### 2.1.2 Metal Complexes of Tetrazoles in Biology

The number of publications and patents describing the synthesis and investigations of the structure and physiochemical properties of metal derivatives with tetrazoles included in their structure has grown intensively. This is due to the wide ranging applications of these compounds which include, but are not limited to, pyrotechniques, organic synthesis and gas generating compositions. ${ }^{2,112}$ One of the most important fields where tetrazolecontaining coordination compounds are used is in medicinal chemistry. The high physiological activity and low toxicity of tetrazoles means that their metal complexes are substances of versatile biochemical and pharmaceutical relevance. ${ }^{7}$ It has been shown that in some cases, the use of metal complexes of biologically active compounds leads to an increase in biological activity. Complexes $\mathrm{Ag}_{2} \mathrm{~L}_{2} \mathrm{Cl}_{2}, \mathrm{ML}_{2} \mathrm{Cl}_{2}$ and $\mathrm{MLCl}(\mathrm{M}=\mathrm{Cu}$ (II), $\mathrm{Co}(\mathrm{II})$, $\mathrm{Ni}(\mathrm{II})$ or $\mathrm{Zn}(\mathrm{II})$ ) containing the antibiotic Cefazolin as the ligand (Figure 2.1), exhibits higher anti-bacterial activity in vitro compared to the free ligand. ${ }^{113} \mathrm{~A}$ similar situation was observed for $\mathrm{Zn}(\mathrm{II}), \mathrm{Cu}(\mathrm{II})$ and $\mathrm{Cd}(\mathrm{II})$ complexes with the antibiotic Cefamandole (Figure 2.1). ${ }^{114}$ Silver tetrazolate and chelate complexes which were synthesised by the reaction of divalent metal salts with tetrazole-containing Schiff bases also have anti-bacterial activity. ${ }^{115}$

Figure 2.1: Structures of complexes (from left to right) of Cefazolin and Cefamandole, and a chelate complex of a Schiff base. All exhibited better biological activity compared to the free ligands. ${ }^{113,114,115}$

The search for tumour growth inhibitors among tetrazoles has led to the targeted synthesis and investigations of tetrazole containing metal complexes for their biological activity. The ruthenium(II) complex $\left[\mathrm{Ru}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)_{2}(5-\mathrm{Ph}-1 H\right.$-tetrazole) $]\left[\mathrm{PF}_{6}\right]$ (Figure 2.2) displayed high anti-tumour activity in promyelocytic leukemia cell lines with a lower value of $\mathrm{IC}_{50}\left(72 \mathrm{~h}, 0.69 \pm 0.16 \mu \mathrm{~mol} \mathrm{~L}^{-1} ; 24 \mathrm{~h}, 0.95 \pm 0.15 \mu \mathrm{~mol} \mathrm{~L}^{-1}\right.$ ) compared to cisplatin. ${ }^{112}$ Complexes of $\mathrm{Pt}(\mathrm{II})$ with tetrazolo[1,5-a]quinolines (Figure 2.2), which are analogs of cisplatin, also exhibit cytotoxic activity against the promyelocytic leukemia cell line HL$60 .{ }^{112}$

Figure 2.2: Structures of simple tetrazole ligands and metal complexes of tetrazoles which exhibited cytotoxic activities. ${ }^{112}$

Most of the presently used contrast agents are coordination compounds of gadolinium(III) with organic tetrazole ligands. ${ }^{1}$ This fact is associated with the high ability of these complexes to decrease proton relaxation time of adjacent water molecules due to dipolar interactions. In recent years, there is an active search for complexes of other paramagnetic metals with the aim of using them instead of higly toxic and expensive gadolinium. It has
been shown that an Fe (II) complex with a macrocycle tetrazolyl-containing ligand is a promising contrast agent (Figure 2.3). ${ }^{116}$ Tetrazolyl-containing lanthanide complexes (Ln $=\mathrm{Eu}, \mathrm{Tb}, \mathrm{Nb}$ ) were also described as potential contrast agents. Polydentate ligands are involved in the formation of such complex compounds (Figure 2.3).117

Figure 2.3: A variety of polydentate tetrazole ligands when complexed to metal ions has resulted in the formation of promising contrast agents. ${ }^{116,117}$

Hence, it can be stated that tetrazole derivatives and their metal complexes have an adequate position in the area of medicinal chemistry. These compounds exhibit diverse biological activities and are attractive entities for investigational drug design.

### 2.1.3 Anti-cancer Activity of Metal Complexed Pyridyl Tetrazoles

McGinley and co-workers have made substantial progress in the area of tetrazole synthesis and metal coordination to tetrazoles. ${ }^{118}$ The group's initial studies involving tetrazoles targeted the use of macrocycles which could be used as molecular sensors for metal ions. In nearly all cases, it was found that the cavity size between the tetrazole rings was very small or almost non-existent, with one noteable exception (Figure 2.4).119 Unfortunately, the metal binding ability of all these macrocycles was not as effective as expected. It was observed that weak binding occurred in solution, but all attempts to isolate and characterise any metal complexes as solids failed as the complexes disintegrated once out of solution.

This work led to the synthesis of macromolecules, instead of macrocycles, which would be capable of binding metal ions. ${ }^{120}$ The McGinley group used a substitution reaction to tether two pyridyl tetrazole units to bis-tetrazoles. These tetrazoles were bridged via a range of bridging units such as alkyl chains, benzyl and heterocyclic rings. To the pyridyl tetrazole unit, a pendant bromohexyl arm was added for easy attachment to the bis-tetrazole unit (Scheme 2.1). The preparation of the pyridyl tetrazole moiety with the pendant
bromohexyl arm was carried out in two steps. Both the $\mathrm{N}-1$ and $\mathrm{N}-2$ isomers (Figure 2.5) were obtained in good yields following chromatographic separation. Transition metal complexes of both compounds were obtained after reactions with several different metal salts. In several cases the complexes were structurally characterised by X-ray crystallography. ${ }^{121}$

Figure 2.4: X-ray crystal structure and space fill model of a macrocycle with a cavity. ${ }^{119}$

(i)

Scheme 2.1: Reagents and conditions: (i) $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{MeCN}, \Delta, 24 \mathrm{~h} . \mathrm{X}=\mathrm{CH}, \mathrm{N} .{ }^{120}$

2.1

2.2

Figure 2.5: Two regioisomers which were synthesised previously in the McGinley group.

The free ligands and their metal complexes were screened against breast, lung, liver and prostate cancer cell lines. Several drug resistant cancer cells lines were also screened. The two copper(II) chloride complexes, one having the pendant arm attached at $\mathrm{N}-1$ of the ligand (2.3) and the other having the arm attached at N -2 (2.4, Figure 2.6), gave a complete kill across the concentration range of the study (unpublished results), which is rare with toxicity testing. Both of the $\mathrm{Cu}(\mathrm{II})$ complexes were very toxic to prostate and breast cancers. Furthermore, the free ligand and free metal salt did not display any significant activity, emphasising the importance of the complex as an entire entity having a key role in its mechanism of action. In addition, the complex showed low $\mathrm{IC}_{50}$ values compared to the free metal salt and ligand, with $\mathrm{IC}_{50}$ values very close to that of cisplatin under the same conditions. Based on these encouraging results, it was proposed to synthesise a library of metal complexes based on the pyridyl tetrazole template. By varying the pendant arm and metal centre, an improvement in the complex's biological activity could be achieved as well as an insight into the complex's mode of action.

2.3

2.4

Figure 2.6: Two $\mathrm{CuCl}_{2}$ complexes which showed particularly good anti-cancer activity.

### 2.2 Aims and Objectives of Chapter

The aim of this body of work was to synthesise a library of ligands with the same metalbinding core as a pyridyl substituted tetrazole and then to alter the pendant arm bonded to the tetrazole ring. Metal complexes would be synthesised from these ligands and different metal salts would also be utilised. The variation in the pendant arm and the metal atom bound would allow an investigation into what functional groups and metals contribute towards the biological activity of the compound. It was intended that a number of variations would be made to these compounds: firstly, the chain length between the tetrazole moiety and the functional group, followed by changing the functional group to methyl groups, alcohols, esters or carboxylic acids and finally to change the metal centre. These derivatives could readily be obtained utilising methods previously established by McGinley and co-workers. Each of these variations would alter the lipophilicity and solubility of the complexes and thus, could affect the biological activity of the complex. The synthesised library could be used in a structure-activity relationship (SAR) study in order to identify the key functionalities which are important for biological activities. Therefore any future variations to the structure of the complexes could be determined.

### 2.3 Results and Discussion

### 2.3.1 Synthesis of Ligands

Synthesis of all pyridyl tetrazole ligands in this chapter was carried out utilising methods previously described by McGinley et al. ${ }^{122}$ The tetrazole moiety is typically obtained via a 1,3-dipolar cycloaddition reaction between an azide and a nitrile, where the azide is employed as the 1,3-dipole, whilst the nitrile is employed as the dipolarophile. This [2+3] cycloaddition occurs by a concerted mechanism (Scheme 2.2).21,123

Scheme 2.2: Concerted mechanism of the 1,3-dipolar cycloaddition of a nitrile and azide. ${ }^{123}$

An alternative method of tetrazole synthesis employs ammonium azides as the 1,3-dipole, and a discussion of this method is covered in section 1.1.2.1. ${ }^{21}$ Synthesis of 2-(2H-tetrazol-5-yl)pyridine (2.5) was achieved under these alternative conditions, by reacting sodium azide and 2-cyanopyridine in the presence of ammonium chloride and lithium chloride in anhydrous DMF (Scheme 2.3). Although the use of 10 equivalents of lithium chloride is reported here, it is noteworthy that reactions attempted with significantly lower equivalents also produced compound 2.5 in good yields. Synthesis of 2.5 was confirmed by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ NMR and IR spectroscopies. IR spectroscopy suggested the consumption of the nitrile with the disappearance of the associated $v(\mathrm{C} \equiv \mathrm{N})$ stretch at $2236 \mathrm{~cm}^{-1}$. The disappearance of a ${ }^{13} \mathrm{C}$ peak at 117.2 ppm in the ${ }^{13} \mathrm{C}$ NMR spectrum also supported this. The ${ }^{13} \mathrm{C}$ NMR spectrum also confirmed the formation of a 1,5-tetrazole ring with a signal at 154.9 ppm arising from the C-5 carbon of the tetrazole ring.

Scheme 2.3: Synthesis of 2.5 was achieved via formation of ammonium azide in situ.

Subsequently, 2.5 was reacted with several bromoalkyl compounds in the presence of $\mathrm{K}_{2} \mathrm{CO}_{3}$ to yield alkylated tetrazoles, with alkylation occurring at either the $\mathrm{N}-1$ or $\mathrm{N}-2$
positions of the ring (Scheme 2.4). The production of two regioisomers arises from the occurrence of tautomerism in tetrazole rings (section 1.1.3). As a result of this phenomenon, when the tetrazole ring is deprotonated, nucleophilic attack can occur from either position, yielding two different products; the $\mathrm{N}-1$ substituted product and the $\mathrm{N}-2$ substituted product.

Scheme 2.4: Synthesis of alkylated tetrazoles gave rise to two regioisomers.

Thin Layer Chromatography (TLC) was carried out on the crude mixture of isomers, and two well separated spots were observed. Therefore, column chromatography was employed to separate the two regioisomers. In the late 1970's, Butler and McEvoy demonstrated that it is possible to distinguish the $\mathrm{N}-1$ from the $\mathrm{N}-2$ isomer by analysis of their ${ }^{13} \mathrm{C}$ NMR and ${ }^{1} \mathrm{H}$ NMR spectra. ${ }^{124,125}$ Employing a variation of organic 5 -aryltetrazoles, they reported that the ${ }^{13} \mathrm{C}$ chemical shift values of the tetrazole carbon (C-5) can determine the annular tautomerism. For 5 -aryltetrazoles, it was observed that the C-5 chemical shift of the $\mathrm{N}-1$ isomer was positioned significantly more upfield ( $\delta \mathrm{C}-5=152-157$ ppm ) when compared to that of the $\mathrm{N}-2$ isomer ( $\delta \mathrm{C}-5=162-167 \mathrm{ppm}) .{ }^{125}$ The two isomers produced by alkylation of 2.5 were readily identifiable by their ${ }^{13} \mathrm{C}$ NMR spectra, with the observation of the tetrazole C-5 resonance signals occurring from 150.1-151.8 ppm for the $\mathrm{N}-1$ isomers, and 164.5-164.9 ppm for the $\mathrm{N}-2$ isomers. These values fit well within the ranges stated by Butler et al. ${ }^{124,125}$

In general, the methyl or alkyl protons of substituents on $\mathrm{N}-1$ substituted tetrazoles are more shielded by $\sim 0.15-0.35 \mathrm{ppm}$ in the ${ }^{1} \mathrm{H}$ NMR spectrum relative to the corresponding $\mathrm{N}-2$ isomer. ${ }^{126}$ This trend is due to the relative electron density of the $-\mathrm{N}=$ moiety over the $-\mathrm{C}=$ moiety relative to the alkyl substituents (Figure 2.7).

Figure 2.7: Order of chemical shifts of alkyl groups (R) in simple azoles.

However, this relationship may break down depending on the substituents present on the carbon of the tetrazole, for example those that possess anisotropic effects. ${ }^{127}$ Throughout the course of this work, the protons of the alkyl group bonded to the tetrazole resonated more downfield in the $\mathrm{N}-1$ isomers when compared to the $\mathrm{N}-2$ isomers. This pattern is in contrast with the trend seen for 5 -aryltetrazoles. However, it is consistent with 5substituted tetrazoles with anisotropic groups in the 5 -position. This phenomenon has been reported previously for pyridyl tetrazoles ${ }^{128}$ and reinstates the findings by Butler et al. that the use of ${ }^{13} \mathrm{C}$ NMR shifts are more reliable than ${ }^{1} \mathrm{H}$ NMR shifts when assigning the position of alkylation on tetrazole rings. ${ }^{124,125,127}$

### 2.3.1.1 Bromoalkyl Chain Derivatives

The products synthesised from the reaction of 2.5 with 1,3-dibromopropane, 1,4dibromobutane, 1,6-dibromohexane and 1,8-dibromooctane in the presence of base yielded waxy orange/brown solids with low melting points. Successful synthesis of the alkylbromo substituted tetrazoles was confirmed by employing ${ }^{1} \mathrm{H}$ NMR spectroscopy on the crude residues. The presence of two regioisomers was immediately evident on observation of the ${ }^{1} \mathrm{H}$ NMR spectra, as twice as many of the expected peaks could be distinguished (Figure 2.8). After purification by column chromatography, each regioisomer exhibited the following signals. Four signals attributed to the pyridyl protons were observed at $\sim 7.40-8.79 \mathrm{ppm}$ and a triplet arising from the methylene group bonded to the tetrazole ring was observed at $\sim 4.70-5.15 \mathrm{ppm}$. A triplet at $\sim 3.39-3.46 \mathrm{ppm}$ was attributed to the methylene group bonded to the terminal bromine atom, with the remaining signals observed from $\sim 1.36-2.08 \mathrm{ppm}$ arising from the remaining protons on the alkyl chain. In all reactions, the $\mathrm{N}-2$ substituted tetrazole was the predominant regioisomer. This could be observed from analysis of the ${ }^{1} \mathrm{H}$ NMR spectra of the crude mixtures as the $\mathrm{CH}_{2}$-tet protons of the $\mathrm{N}-1$ regioisomers resonated significantly more downfield when compared to the respective signals of the $\mathrm{N}-2$ regioisomer. Therefore a comparison of their relative integrations was possible (Figure 2.8). The slight difference in the observed regioselectivity can be accredited to the features of their structures.

Pokhodylo and co-workers carried out quantum-chemical optimisation of geometries of chloroacetamide alkylated 5-substituted aryl tetrazoles. ${ }^{129}$ Experimental data indicated that a co-planar arrangement of the benzene and tetrazole rings was not probable in the 1,5 -regioisomers due to the steric hindrance inflicted by the substituent at the $\mathrm{N}-1$ position, causing the benzene ring to deviate from the plane of the molecule (Figure 2.9).

2.10

2.11

Figure 2.8: Crude ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{CDCl}_{3}$ of $\mathbf{2 . 1 0}$ and $\mathbf{2 . 1 1}$ mixture. Methylene protons beside the tetrazole ring (denoted with ${ }^{*}$ ) resonated at significantly different chemical shifts, allowing a comparison of regioselectivity to be carried out.

The 2,5-regioisomers experience no steric hindrance due to the substituent, and therefore the benzene and tetrazole rings can exist in the same plane. This slight steric hindrance is thought to explain the regioselectivity towards $\mathrm{N}-2$ substitution in the alkylation of 2.5. ${ }^{129}$ A ratio of $10: 13$ was obtained from the bromooctyl (2.10, 2.11), bromohexyl (2.1, 2.2) and bromobutyl $(2.8,2.9)$ crude mixtures. However, in the case of the bromopropyl derivatives (2.6, 2.7), the regioselectivity for the formation of the $\mathrm{N}-2$ isomer was more prominently evident, with a ratio of $10: 33$ observed. An increase in steric hindrance is likely to be brought about by the closer proximity of the large bromine atom to the ring systems when compared to the longer chain derivatives.

Figure 2.9: The steric structure of the regioisomers obtained through a semi-emperical PM3 method. ${ }^{129}$

In order to see if the cation of the base had any effect on the regioselectivity of the reaction, an experiment employing 2.5, 1,6-dibromohexane and $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ as the base was carried out. ${ }^{1} \mathrm{H}$ NMR spectra of the crude mixtures revealed that even though $\mathrm{Cs}^{+}$was a bigger cation, the use of $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ had no effect on the regioselectivity in the alkylation reaction using 1,6-dibromohexane. In fact, a ratio of $10: 12$ was observed for the $\mathrm{N}-1$ and $\mathrm{N}-2$ isomers; a relative decrease in the yield of the $\mathrm{N}-2$ isomer.

### 2.3.1.2 Alkyl Chain Derivatives

Synthesis of alkyl chain substituted pyridyl tetrazoles yielded products 2.12-2.17 as oils. All derivatives were characterised by ${ }^{1} \mathrm{H}$ NMR, ${ }^{13} \mathrm{C}$ NMR and IR spectroscopies and HRMS. In the ${ }^{1} \mathrm{H}$ NMR spectra of the products, four signals were observed at $\sim 8.79-7.39 \mathrm{ppm}$ which were attributed to the pyridyl protons. A triplet that integrated for two protons appeared at $\sim 4.70-5.03 \mathrm{ppm}$ which was assigned to the $\mathrm{CH}_{2}$-tet protons, which were the only alkyl chain protons expected to resonate at this downfield position. The remaining signals at $\sim 0.87-2.00 \mathrm{ppm}$ were assigned to the remaining alkyl chain protons. It was again evident from the ${ }^{1} \mathrm{H}$ NMR spectra that the $\mathrm{N}-2$ substituted products were the marginally major products, with ratios of 10:13 observed in all cases. When the lack of significant regioselectivity observed in the formation of products 2.12-2.17 is compared to the regioselectivity seen in the formation of the bromopropyl derivatives $\mathbf{2 . 6}$ and $\mathbf{2 . 7}$, it is evident that the presence of the bromine atom in these derivatives influenced the regioselectivity of the alkylation reaction to some extent.

### 2.3.1.3 Alcohol Chain Derivatives

Access to compounds 2.18-2.25 was achieved by reacting 2.5 with either 3-bromo-1propanol, 4-bromo-1-butanol, 6-bromo-1-hexanol or 8-bromo-1-octanol in the presence of
base. After work-up and separation of the regioisomers by column chromatography, products were afforded as either low melting white-yellow solids or oils. The typical ${ }^{1} \mathrm{H}$ NMR spectra for these compounds possessed four aromatic pyridyl proton signals resonating at $\sim 7.40-8.78 \mathrm{ppm}$, a triplet at $\sim 4.72-5.03 \mathrm{ppm}$ representing the $\mathrm{CH}_{2}$-tet protons, a triplet arising from the methylene protons adjacent to the alcohol group at $\sim 3.62-3.88 \mathrm{ppm}$ and remaining signals were attributed to the alkyl chain. The chemical shift of the alcohol proton varied depending on its proximity to the tetrazole ring, with the shorter chain derivatives resulting in a downfield shift. The hydroxy proton peak also differed in splitting pattern, sometimes appearing as a triplet and other times as a broad singlet. The signal arising from this proton was easily identifiable when not overlapping with other signals, as it was the only signal integrating for one proton. Figure 2.10 presents a ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{2 . 1 8}$ with all relevant signals labelled. Assignment of protons was determined by carrying out COSY spectroscopy. The presence of the alcohol group was also evident in the IR spectrum of the compounds, with a broad OH stretch observed at $\sim 3310-3400 \mathrm{~cm}^{-1}$ and a strong absorption at $\sim 1055 \mathrm{~cm}^{-1}$ which is a characteristic absorption of a $\mathrm{C}-0$ bond in an alcohol. There was no significant variation in the regioselectivity of these alkylation reactions with $\mathrm{N}-1$ and $\mathrm{N}-2$ isomers being produced in a ratio of 10:13.

Figure 2.10: ${ }^{1} \mathrm{H}$ NMR spectrum carried out in $\mathrm{CDCl}_{3}$ of $\mathbf{2 . 1 8}$ with relevant proton peaks labelled. Peak at 1.56 ppm arises from residual $\mathrm{H}_{2} \mathrm{O}$ in deuterated solvent.

### 2.3.2 Synthesis of Metal Complexes

Metal complexes were synthesised by reacting a 1:1 stoichiometric ratio of metal salt to ligand in MeOH at reflux temperature for 2 hours. The solutions were then allowed to
stand for several days and the solids that formed were isolated and washed with MeOH . Metal salts used included $\mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}, \mathrm{ZnCl}_{2}, \mathrm{NiCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{Co}(\mathrm{SCN})_{2}$.

### 2.3.2.1 Metal Complexes of Bromoalkyl Derivatives

### 2.3.2.1.1 Copper(II) chloride dihydrate reactions

On addition of $\mathrm{CuCl}_{2} 2 \mathrm{H}_{2} \mathrm{O}$ to methanolic solutions of bromoalkyl derivatives 2.6-2.11, vibrant green coloured solutions were observed, with green crystalline solids or powders forming on slow evaporation of the reaction solution. On noting the colour of the solids, further confirmation that copper was complexed to the ligands was achieved by carrying out IR spectroscopy on the green solids. The resulting spectra were compared to those of their respective starting materials and were interpreted in accordance with literature examples of chelating pyridyl-containing azoles, ${ }^{130} \mathrm{~N}$-alkyltetrazoles and their metal complexes. ${ }^{131}$ Characteristic frequencies of the bromoalkyl functionalised pyridyl tetrazoles and their $\mathrm{Cu}(\mathrm{II})$ complexes are shown in Table 2.1. Coordination of metal ions leads to significant changes in the frequencies of the $v(\mathrm{C}=\mathrm{N})$ bands of the pyridine and tetrazole rings which are typically located in the region $1640-1450 \mathrm{~cm}^{-1}$. On analysis of the IR spectra of the uncoordinated ligands and their metal complexes, these vibrational bands shifted to different wavenumbers on complexation to $\mathrm{Cu}(\mathrm{II})$ which suggested that the ligand molecules were coordinating to the metal centre through chelation of both the pyridine and tetrazole nitrogens.

| $\mathbf{2 . 3 1}$ | 1621 | 1462 | 1449 |

Previous work carried out by the McGinley group on the bromohexyl derivatives, $\mathbf{2 . 1}$ and 2.2, yielded crystal structures of $\mathrm{Cu}(\mathrm{II})$ complexes (Figure 2.11). ${ }^{121}$ These structures showed that both $\mathrm{N}-1$ and $\mathrm{N}-2$ isomers consisted of dichloro-bridged dimeric units, with the coordination sphere around each atom comprising one pyridine N atom, one tetrazole

N atom and three Cl atoms. The IR spectra of the complexes synthesised in this body of work suggested a resemblance to these structures. Room temperature magnetic moment measurements gave $\mu_{\text {eff }}$ values in the range of 1.7-2.3 B.M., indicating a $2+$ oxidation state of the metal ion. Furthermore, elemental analysis on the metal complexes suggested a $1: 1$ metal to ligand composition, therefore further indicating that the complexes synthesised were analogous to those in Figure 2.11. A representation of the structures can be seen in Figure 2.12.

### 2.3.2.1.2 Nickel(II) chloride hexahydrate reactions

Nickel(II) complexes were synthesised in a similar manner to that utilised for the copper(II) complexes, with green coloured reaction solutions producing green solids on slow reduction of the mother liquor. Room temperature magnetic moment measurements
indicated that the complex had two unpaired electrons with $\mu_{\text {eff }}$ values in the range of 2.94.2 B.M., which eliminated square planar geometry from our consideration. Hence, the structures of the $\mathrm{Ni}(\mathrm{II})$ complexes were believed to be of either tetrahedral (4-coordinate) or square pyramidal/trigonal bipyramidal (5-coordinate) geometry. IR spectroscopy established that the $\mathrm{Ni}(\mathrm{II})$ metal centre was coordinating to the pyridine N atom and tetrazole N atoms as $v(\mathrm{C}=\mathrm{N})$ bands arising from the tetrazole rings had shifted from $\sim 1580 \mathrm{~cm}^{-1}$ to higher wavenumbers, and $v(\mathrm{C}=\mathrm{N})$ bands arising from the pyridine ring had also shifted (Table 2.2).

| 2.36 | 1608 | 1478 | 1457 |
| 2.2* | 1598 | 1518 | 1438 |
| 2.37 | 1615 | 1451 | 1261 |
| 2.10* | 1593 | 1467 | 1417 |
| 2.38 | 1606 | 1478 | 1459 |
| 2.11* | 1593 | 1466 | 1416 |
| 2.39 | 1614 | 1463 | 1452 |

Elemental analysis of the complexes yielded a ratio of 1:1 metal to ligand composition. In considering the geometrical preferences for $\mathrm{Ni}(\mathrm{II})$, it is well known that there are several examples of tetrahedral and square pyramidal/trigonal bipyramidal $\mathrm{Ni}(\mathrm{II})$ complexes. ${ }^{132}$ However, high spin paramagnetic trigonal bipyramidal Ni(II) complexes are rare, ${ }^{132}$ and the manifestation of an intrinsic magnetic moment had to be taken into account. Evidence of bridging or terminal chloride bonds could not be determined due to the presence of other frequencies in the fingerprint region. Despite numerous attempts, no X-ray quality crystals of these complexes were obtained. Therefore, it was tentatively proposed that the $\mathrm{Ni}(\mathrm{II})$ complexes formed coordination compounds that were either analogous to the $\mathrm{Cu}(\mathrm{II})$ complexes seen in Figure 2.11, with the $\mathrm{Ni}(\mathrm{II})$ centre possessing a square pyramidal geometry, or formed a tetrahedral $\mathrm{Ni}(\mathrm{II})$ complex. The latter would be deemed most likely as high spin tetrahedral complexes of $\mathrm{Ni}(\mathrm{II})$ are more prevalent in the literature. ${ }^{132} \mathrm{~A}$ representation of the proposed complexes can be seen in Figure 2.13.

### 2.3.2.1.3 Cobalt(II) thiocyanate reactions

Pink or blue solutions were observed in all reactions involving cobalt(II) thiocyanate, with crystalline rust coloured solids being collected after reduction of the reaction solution. As a $3 \mathrm{~d}^{7}$ system, $\mathrm{Co}(\mathrm{II})$ complexes have 3 unpaired electrons and would have a calculated spin-only magnetic moment of 3.8 B.M. for high spin complexes. Octahedral complexes typically have magnetic moments between 4.7 and 5.2 B.M. Tetrahedral complexes are typically below 4.7 B.M. but may be higher for stronger field ligands. Thus, magnetic moments give some indication of geometry but are not completely reliable. Magnetic susceptibility measurements at room temperature recorded $\mu_{\text {eff }}$ values in the range of 4.65.5 B.M., indicating the presence of high spin octahedral Co(II) ions. The IR spectra showed clear indications that complexation to the ligands had occurred (Table 2.3). Coordination to the heterocyclic N atoms was confirmed due to shifting of the $v(\mathrm{C}=\mathrm{N})_{\text {tet }}$ band from $\sim 1580 \mathrm{~cm}^{-1}$ to $\sim 1610 \mathrm{~cm}^{-1}$ and shifting of the $v(\mathrm{C}=\mathrm{N})_{\text {pyr }}$ stretch. The presence of thiocyanate groups were revealed in the IR spectra due to an intense absorption at $\sim 2077$ $\mathrm{cm}^{-1}$ attributed to the asymmetric vibration $v(\mathrm{C}-\mathrm{N})_{\mathrm{scN}}$, which had shifted from $2152 \mathrm{~cm}^{-1}$ in the metal salt $\operatorname{Co}(\mathrm{SCN})_{2}$. Elemental analysis of the rust coloured complexes implied that they had a 1:2 metal to ligand composition. It was proposed that the Co(II) complexes were congeners to those synthesised previously by McGinley et al. ${ }^{121}$ These complexes
consisted of an octahedral Co(II) centre that was coordinated to two pyridyl tetrazole ligands, with two thiocyanate anions balancing the $2+$ charge on the metal centre (Figure 2.14). These proposed structures are represented in Figure 2.15.

### 2.3.2.1.4 Zinc(II) chloride reactions

Complexation reactions with zinc(II) chloride yielded cream, yellow or orange compounds and generally were the same colour as the starting ligand. Longer reaction times were required in order for $\mathrm{ZnCl}_{2}$ to complex to the ligand, therefore 12 hour reaction times were employed. IR spectroscopy was carried out on the $\mathrm{Zn}(\mathrm{II})$ complexes and compared to the spectra of their respective starting materials. In all spectra a shift of the $v(\mathrm{C}=\mathrm{N})$ frequencies of the pyridine and tetrazole ring was observed. In the IR spectra of the ligands, these vibrational bands could be found at $\sim 1471-1500 \mathrm{~cm}^{-1}$ and these shifted to $\sim 1500-1600 \mathrm{~cm}^{-1}$ on complexation of $\mathrm{Zn}(\mathrm{II})$ (Table 2.4). Elemental analysis suggested a 1:1 metal to ligand composition, therefore, it was postulated that a dichloro-bridged species similar to the $\mathrm{Cu}(\mathrm{II})$ complexes were present (Figure 2.11) as a coordination number of 5 is most common for $\mathrm{Zn}(\mathrm{II})$ complexes. ${ }^{132}$ The structures of the proposed complexes can be seen in Figure 2.16.

Due to $\mathrm{Zn}(\mathrm{II})$ ions being diamagnetic, NMR spectroscopy was also carried out on the complexes. ${ }^{1} \mathrm{H}$ NMR spectra of the zinc(II) chloride complexes were all obtained in $\mathrm{CDCl}_{3}$. Table 2.5 shows the ${ }^{1} \mathrm{H}$ NMR spectral data for the four pyridyl tetrazole ligands with the alkyl bromides attached at the $\mathrm{N}-1$ position and the four corresponding zinc(II) chloride complexes, while Table 2.6 contains the ${ }^{1} \mathrm{H}$ NMR spectral data for the four pyridyl tetrazole ligands with the alkyl bromides attached at the $\mathrm{N}-2$ position and the four corresponding zinc(II) chloride complexes.

From the data obtained, it is evident that binding of the zinc chloride has a greater effect on the protons in the series of N -2 ligands, as seen from the larger differences in chemical shift for both the pyridyl proton signals and the signal for the methylene group attached to the tetrazole ring. The ${ }^{1} \mathrm{H}$ NMR spectra of the $\mathrm{Zn}(\mathrm{II})$ complexes from the $\mathrm{N}-1$ series of ligands shows only slight variation in signal position compared to the starting ligands. It has previously been observed that the complexation properties of 1- and 2-substituted tetrazole isomers differ greatly due to the electronic properties of the tetrazole ring being influenced by alkyl substituents. ${ }^{131}$ Hence, it is proposed that the manifestation of such large differences are due to the differing electronic properties of the $\mathrm{N}-1$ and $\mathrm{N}-2$ isomers.

### 2.3.2.2 Metal Complexes of Alkyl Chain Derivatives

### 2.3.2.2.1 Copper(II) chloride dihydrate reactions

Reactions with $\mathrm{CuCl}_{2} 2 \mathrm{H}_{2} \mathrm{O}$ resulted in solutions of the ligands turning a vibrant green colour. These solutions produced crystalline green solids on reduction of the mother liquor at room temperature. IR spectra of the green solids indicated that complexation to the pyridine and tetrazole nitrogens had occurred, as $v(\mathrm{C}=\mathrm{N})$ bands from the pyridine and tetrazole rings had shifted (Table 2.7).

Table 2.7: Selected IR frequencies of free ligands* and $\mathrm{Cu}(\mathrm{II})$ complexes.

| Compound | $\mathrm{C}=\mathrm{N}_{\text {tet }}\left(\mathrm{cm}^{-1}\right)$ | $\mathrm{C}=\mathrm{N}_{\text {pyr }}\left(\mathrm{cm}^{-1}\right)$ | $\mathrm{N}=\mathrm{N}\left(\mathrm{cm}^{-1}\right)$ |

| $\mathbf{2 . 1 7}$ | 1593 | 1466 | 1419 |
| $\mathbf{2 . 5 9}$ | 1616 | 1537 | 1454 |

Room temperature magnetic moment measurements yielded expected $\mu_{\text {eff }}$ values in the range of 1.8-2.1 B.M. indicating the presence of $\mathrm{d}^{9} \mathrm{Cu}(\mathrm{II})$ metal centres. A ratio of 1:1 metal to ligand ratio was suggested in elemental analysis results, therefore it was postulated that
these Cu (II) complexes had the same structure as those depicted in Figure 2.11. These proposed structures can be seen in Figure 2.17.

$2.59 \mathrm{n}=7$

Figure 2.17: Proposed structures of compounds 2.54-2.59.

### 2.3.2.2.2 Nickel(II) chloride hexahydrate reactions

Green solutions were observed in reactions with $\mathrm{NiCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ and green or blue solids were recovered from these solutions on slow evaporation of the mother liquor. Room temperature magnetic moment measurements yielded $\mu_{\text {eff }}$ values in the ranges of 3.1-4.3 B.M., which eliminated square planar geometry from our consideration but did indicate the presence of high spin $\mathrm{Ni}(\mathrm{II})$ centres, and conformed with those reported for high spin five-coordinate $\mathrm{Ni}(\mathrm{II})$ complexes. ${ }^{133}$ IR spectroscopy suggested that the coordination geometry around the $\mathrm{Ni}(\mathrm{II})$ centre involved the pyridine and tetrazole nitrogens as shifts could be seen in the characteristic heterocyclic bands (Table 2.8).

Table 2.8: Selected IR frequencies of free ligands* and Ni(II) complexes.

| Compound | $\mathrm{C}=\mathrm{N}_{\text {tet }}\left(\mathrm{cm}^{-1}\right)$ | $\mathrm{C}=\mathrm{N}_{\text {pyr }}\left(\mathrm{cm}^{\mathbf{- 1}}\right)$ | $\mathrm{N}=\mathrm{N}\left(\mathrm{cm}^{-\mathbf{1}}\right)$ |

| $\mathbf{2 . 6 1}$ | 1611 | 1479 | 1457 |
| $\mathbf{2 . 1 4}$ | 1592 | 1434 | 1421 |
| $\mathbf{2 . 6 2}$ | 1613 | 1479 | 1456 |
| $\mathbf{2 . 1 5}$ | 1595 | 1466 | 1420 |
| $\mathbf{2 . 6 3}$ | 1614 | 1461 | 1452 |
| $\mathbf{2 . 1 6}$ | 1591 | 1467 | 1433 |
| $\mathbf{2 . 6 4}$ | 1611 | 1479 | 1456 |
| $\mathbf{2 . 1 7}$ | 1593 | 1466 | 1419 |
| $\mathbf{2 . 6 5}$ | 1615 | 1461 | 1452 |

Elemental analysis revealed a 1:1 metal to ligand ratio. Therefore, it was proposed that there were two $\mathrm{Ni}(\mathrm{II})$ centres of square pyramidal geometry which were bridged by two chloride atoms, similar to those discussed previously and shown in Figure 2.11. The structures of the proposed complexes can be seen in Figure 2.18. It must also be stated that tetrahedral geometry would also fit the data obtained, however assignments to either geometry was hampered by the fact that metal-chloride (terminal or bridging) IR frequencies could not be distinguished due to their presence in the fingerprint region.

Figure 2.18: Proposed structures of compounds 2.60-2.65.

### 2.3.2.2.3 Cobalt thiocyanate reactions

Reactions with cobalt(II) thiocyanate resulted in pink or royal blue solutions. Rust coloured solids were produced on slow evaporation of the reaction solvent. Magnetic measurements at room temperature yielded $\mu_{\text {eff }}$ values of $\sim 5.0$ B.M. which indicated that the geometry of the Co(II) ion was octahedral. IR spectra once again strongly suggested coordination to the pyridyl and tetrazole nitrogens, with the significant shifts observed presented in Table 2.9. Presence of thiocyanate anions were also revealed in the IR spectra.

| $\mathbf{2 . 1 3}$ | 1609 | 1478 | 1456 | 2068 |
| $\mathbf{2 . 6 7}$ | 1594 | 1466 | 1419 |  |
| $\mathbf{2 . 1 4}$ | 1610 | 1458 | 1447 | 2077 |
| $\mathbf{2 . 6 8}$ | 1592 | 1434 | 1421 |  |
| $\mathbf{2 . 1 5}$ | 1609 | 1476 | 1456 | 2067 |
| $\mathbf{2 . 6 9}$ | 1595 | 1466 | 1420 |  |
| $\mathbf{2 . 1 6}$ | 1609 | 1459 | 1447 | 2074 |
| $\mathbf{2 . 7 0}$ | 1591 | 1467 | 1433 |  |
| $\mathbf{2 . 1 7}$ | 1610 | 1476 | 1457 | 2068 |
| $\mathbf{2 . 7 1}$ | 1593 | 1466 | 1419 |  |

On slow evaporation of the reaction solvent, crystalline solids of 2.67 and 2.71 were produced which were suitable for X-ray crystallography. The molecular structures are depicted in Figures 2.19 and 2.20. In both structures, the Co(II) atom has an octahedral geometry with the pyridyl tetrazole ligands chelating in the equatorial plane with the two isothiocyanate anions coordinating along the axial direction. Each pyridyl tetrazole ligand binds to the $\operatorname{Co(II)}$ atom through one tetrazole nitrogen atom at the $\mathrm{N}-1$ site and through the pyridyl nitrogen atom. The pyridine rings are not co-planar with the tetrazole rings giving both complexes a slightly puckered conformation. The planes between the pyridine and tetrazole rings form interplanar angles of $3.8(5)^{\circ}$ and $1.6(5)^{\circ}$ in 2.67 and $4.5(4)^{\circ}$ in 2.71. The Co-N $\mathrm{N}_{\mathrm{NCS}}$ distances are in the range from $2.037(6)$ to $2.060(6) \AA$, whereas the remaining Co-N distances are $0.10 \AA$ longer and in the range of 2.140 (4) to 2.170 (3) $\AA$.

Figure 2.19: A view of 2.67 with atoms depicted with displacement ellipsoids at their 20\% probability level.

These bond lengths are typical of $\mathrm{Co}(\mathrm{II})-\mathrm{N}$ distances involving isothiocyanate and heteroaromatic ring donor groups. The isothiocyanate moieties in both complexes are
regular with NCS angles of $178.5(6)^{\circ}, 176.9(5)^{\circ}$ and $178.5(4)^{\circ}$. In $\mathbf{2 . 6 7}$, the coordination geometry is close to ideal octahedral, with all three trans angles within $1^{\circ}$ of $180^{\circ} .2 .71$ resides with the cobalt atom on inversion centres and trans $\mathrm{N}-\mathrm{Co}-\mathrm{N}$ angles of $180^{\circ}$.

Figure 2.20: A view of $\mathbf{2 . 7 1}$ with atoms depicted with displacement ellipsoids at the $20 \%$ probability level; only one component of the disordered $n$-octyl chain is shown.

As a result of X-ray crystallography demonstrating that these octahedral Co(II) complexes were formed and furthermore, due to satisfactory data being obtained for other Co(II) complexes, it was proposed that all Co(II) complexes of alkyl chain functionalised pyridyl tetrazoles were of this type (Figure 2.21).

$$

$2.69 \mathrm{n}=5$
$2.71 \mathrm{n}=7$

Figure 2.21: Proposed structures of compounds 2.66-2.71.

### 2.3.2.2.4 Zinc(II) chloride reactions

Reactions with zinc(II) chloride yielded white or orange solids. IR spectra of the solids indicated that Zn (II) was coordinating to the pyridyl and tetrazole nitrogens as shifts were observed for the characteristic heterocyclic stretches (Table 2.10).

Table 2.10: Selected IR frequencies of free ligands and $\mathrm{Zn}(\mathrm{II})$ complexes.

| Compound | $\mathrm{C}=\mathrm{N}_{\mathrm{tet}}\left(\mathrm{cm}^{-1}\right)$ | $\mathrm{C}=\mathrm{N}_{\mathrm{pyr}}\left(\mathrm{cm}^{-1}\right)$ | $\mathrm{N}=\mathrm{N}\left(\mathrm{cm}^{-1}\right)$ |

| $\mathbf{2 . 7 3}$ | 1614 | 1547 | 1453 |
| $\mathbf{2 . 1 4}$ | 1592 | 1434 | 1421 |
| $\mathbf{2 . 7 4}$ | 1610 | 1480 | 1460 |
| $\mathbf{2 . 1 5}$ | 1595 | 1466 | 1420 |
| $\mathbf{2 . 7 5}$ | 1613 | 1547 | 1454 |
| $\mathbf{2 . 1 6}$ | 1591 | 1467 | 1433 |
| $\mathbf{2 . 7 6}$ | 1610 | 1481 | 1460 |
| $\mathbf{2 . 1 7}$ | 1593 | 1466 | 1419 |
| $\mathbf{2 . 7 7}$ | 1610 | 1543 | 1452 |

NMR spectroscopy was also carried out on the solids and all spectra were obtained in $\mathrm{CDCl}_{3}$. On visual inspection, there were clear differences between the spectra of the ligands and the spectra of the $\mathrm{Zn}(\mathrm{II})$ complexes. Figure 2.22 displays two ${ }^{1} \mathrm{H}$ NMR spectra; the free ligand (blue) is that of $\mathbf{2 . 1 3}$ and the green spectrum is that of the Zn (II) complex 2.73. The four pyridyl protons are observed to shift downfield in the metal complex, with the $\mathrm{CH}_{2}$-tet protons slightly shifting downfield. On comparing NMR data for $\mathrm{N}-1$ and $\mathrm{N}-2$ substituted isomers, it was noted that the $\mathrm{CH}_{2}$-tet protons shifted upfield for $\mathrm{N}-1$ isomers and downfield for N - 2 isomers (Tables 2.11 and 2.12).

Figure 2.22: Comparison of ${ }^{1} \mathrm{H}$ NMR spectra of free ligand 2.13 (blue) and Zn (II) complex 2.73 (green). Spectra obtained in $\mathrm{CDCl}_{3}$.

Also apparent when comparing the two regioisomers was that the pyridyl protons shifted more significantly for the $\mathrm{N}-1$ isomers than the $\mathrm{N}-2$ isomers, which is contrary to what occurred with the alkylbromo congeners.

### 2.3.2.3 Metal Complexes of Alcohol Chain Derivatives

### 2.3.2.3.1 Copper(II) chloride dihydrate reactions

All reactions with $\mathrm{CuCl}_{2} 2 \mathrm{H}_{2} \mathrm{O}$ resulted in green coloured solutions which produced green solids upon slow evaporation of the mother liquor. The IR spectra of the complexes exhibited the trends seen for the previous metal(II) chlorides, with increased wavenumbers observed for characteristic heterocyclic bands (Table 2.13). This again indicated that coordination was occurring at the pyridine and tetrazole nitrogen atoms. Magnetic moment measurements at room temperature were in the range of 1.7-2.3 B.M. which was typical of a $\mathrm{d}^{9} \mathrm{Cu}(\mathrm{II})$ atom. Elemental analysis of the compounds implied a $1: 1$ metal to ligand composition, therefore it was proposed that the $\mathrm{Cu}(\mathrm{II})$ complexes synthesised were analogous to those synthesised previously (section 2.3.2.1.1). These proposed structures can be seen in Figure 2.24.

### 2.3.2.3.2 Nickel(II) chloride hexahydrate reactions

All reactions with nickel(II) chloride yielded green solutions and on slow evaporation of the mother liquor produced green or blue solids. Reactions were not carried out with the butanol derivatives $\mathbf{2 . 2 0}$ and $\mathbf{2 . 2 1}$ due to the poor yields observed for these ligands. IR spectra of the complexes displayed the same trends experienced for all previously discussed metal(II) chloride complexes. Characteristic heterocyclic band frequencies and their shifts to higher frequencies can be seen in Table 2.14.

Table 2.14: Selected IR frequencies of free ligands* and $\mathrm{Ni}(\mathrm{II})$ complexes.

| Compound | $\mathrm{C}=\mathrm{N}_{\text {tet }}\left(\mathrm{cm}^{-1}\right)$ | $\mathrm{C}=\mathrm{N}_{\text {pyr }}\left(\mathrm{cm}^{-1}\right)$ | $\mathrm{N}=\mathrm{N}\left(\mathrm{cm}^{-1}\right)$ |
| :--- | :---: | :---: | :---: |
| $\mathbf{2 . 1 8}$ | 1591 | 1473 | 1435 |
| $\mathbf{2 . 8 6}$ | 1610 | 1480 | 1461 |
| $\mathbf{2 . 1 9}$ | 1598 | 1435 | 1421 |
| $\mathbf{2 . 8 7}$ | 1615 | 1552 | 1453 |
| $\mathbf{2 . 2 2}$ | 1591 | 1472 | 1433 |
| $\mathbf{2 . 8 8}$ | 1610 | 1482 | 1458 |
| $\mathbf{2 . 2 3}$ | 1599 | 1468 | 1421 |
| $\mathbf{2 . 8 9}$ | 1615 | 1549 | 1454 |
| $\mathbf{2 . 2 4}$ | 1591 | 1471 | 1433 |
| $\mathbf{2 . 9 0}$ | 1608 | 1474 | 1452 |
| $\mathbf{2 . 2 5}$ | 1599 | 1468 | 1421 |
| $\mathbf{2 . 9 1}$ | 1614 | 1547 | 1454 |

Magnetic moments recorded at room temperature yielded $\mu_{\text {eff }}$ values of $4.0-4.5$ B.M. Elemental analysis gave a ratio of 1:1 metal to ligand composition. Hence, it was proposed that the structure of these $\mathrm{Ni}(\mathrm{II})$ complexes were either of a tetrahedral or a square pyramidal nature. Unequivocal evidence in order to clarify what geometry existed was not possible to obtain, as bridging metal-chloride and terminal metal-chloride IR frequencies
were present in the fingerprint region and were difficult to distinguish. The proposed structures of these complexes can be seen in Figure 2.25.

### 2.3.2.3.3 Cobalt(II) thiocyanate reactions

All reactions with $\operatorname{Co}(\mathrm{SCN})_{2}$ were pink in colour and yielded orange or pink crystalline solids. The IR spectra of the complexes exhibited the same indicative band shifts as seen in previously synthesised $\operatorname{Co}(\mathrm{SCN})_{2}$ complexes. The heterocyclic bands shifted to higher frequencies (Table 2.15) and the presence of thiocyanate anions coordinated to the metal centre was revealed through the observation of the $v(\mathrm{C}-\mathrm{N})_{\mathrm{scN}}$ stretch moving to lower frequencies.

Table 2.15: Selected IR frequencies of free ligands*, metal salt $\operatorname{Co}(\mathrm{SCN})_{2}$ and $\operatorname{Co}(\mathrm{II})$ complexes.

| Compound | $\mathrm{C}=\mathrm{N}_{\text {tet }}\left(\mathrm{cm}^{-1}\right)$ | $\mathrm{C}=\mathrm{N}_{\mathrm{pyr}}\left(\mathrm{cm}^{-1}\right)$ | $\mathrm{N}=\mathrm{N}\left(\mathrm{cm}^{-\mathbf{1}}\right)$ | $(\mathrm{C}-\mathrm{N})_{\mathrm{scN}}\left(\mathrm{cm}^{-1}\right)$ |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{Co}(\mathrm{SCN})_{2}$ |  |  |  | 2152 |
| 2.18* | 1591 | 1473 | 1435 |  |
| 2.92 | 1607 | 1480 | 1447 | 2085 |
| 2.19* | 1598 | 1435 | 1421 |  |
| 2.93 | 1610 | 1543 | 1449 | 2084 |
| 2.22* | 1591 | 1472 | 1433 |  |
| 2.94 | 1608 | 1479 | 1461 | 2095 |
| 2.23* | 1599 | 1468 | 1421 |  |
| 2.95 | 1610 | 1476 | 1448 | 2077 |
| 2.24* | 1591 | 1471 | 1433 |  |
| 2.96 | 1609 | 1477 | 1456 | 2067 |
| 2.25* | 1599 | 1468 | 1421 |  |
| 2.97 | 1610 | 1476 | 1448 | 2081 |

Elemental analysis of the compounds indicated a 1:2 metal to ligand ratio, therefore it was proposed that all Co(II) complexes in the alkyl alcohol series were of octahedral geometry, with two pyridyl tetrazole ligands and two thiocyanate groups coordinating to the metal centre (Figure 2.26). The attainment of magnetic moment measurements at room temperature yielded values of 4.8-5.5 B.M., which also supported the presence of an octahedral $\mathrm{Co}(\mathrm{II})$ centre.

$2.93 \mathrm{n}=3$
$2.94 \mathrm{n}=6$
$2.95 \mathrm{n}=6$
$2.96 \mathrm{n}=8$
$2.97 \mathrm{n}=8$

Figure 2.26: Proposed structures of compounds 2.92-2.97.

### 2.3.2.3.4 Zinc(II) chloride reactions

Reactions with zinc(II) chloride were carried out under reflux conditions in MeOH for varying times ( $2 \mathrm{~h}, 24 \mathrm{~h}, 3 \mathrm{~d}$ ). In all cases only free ligand formed in the mother liquor, and this was clearly evident from the ${ }^{1} \mathrm{H}$ NMR spectra of the precipitates formed. The solubility of the alcohol derivatives could have been sufficiently different from other alkylated pyridyl tetrazoles that it nucleated and formed a solid first before binding to the $\mathrm{d}^{10}$ metal ion.

### 2.3.3 In vivo Compound Tolerance in Galleria mellonella

### 2.3.3.1 Insects as in vivo Models for Testing New Drug Candidates

Insects and mammals have been shown to share many similarities in their innate immune systems. ${ }^{134,135}$ For example, the cuticle of insects provides a physical barrier preventing the entry of pathogens, a feature similar to the skin of animals. ${ }^{134,135}$ When a pathogen enters the human body, cells known as macrophages and neutrophils can bind to the microbe and engulf them in a process known as phagocytosis. ${ }^{136}$ In insects, within the haemolymph (analogous to blood of mammals), haemocytes or blood cells are responsible
for the phagocytosis of foreign bodies. ${ }^{134}$ These similarities, along with many others, between the innate immune system of insects and mammals have led to the use of insects as in vivo models for investigating the virulence of many human pathogens and to evaluate the tolerance of novel therapeutic agents. ${ }^{137,138,139}$ An important phase in drug discovery is the assessment of the toxicity of new drug candidates. Before a new drug candidate can reach the clinic it needs to be tested to ensure it is safe and effective. ${ }^{140}$ Toxicity testing is usually carried out using animal models such as mice, rabbits, dogs and monkeys. ${ }^{140}$ However, the use of mammalian models is expensive, labour intensive, time consuming and requires full ethical consideration. Insects such as Galleria mellonella (G. mellonella) are lower in cost, do not require a large amount of storage space or experimental work and can give results within 24 to 48 h . These advantages, in combination with the similarity to the mammalian innate immune system render insects a useful preliminary model for the in vivo testing of new drug candidates and the evaluation of the therapeutic effect of novel anti-microbial agents. Desbois et al. have shown that the treatment of $G$. mellonella infected with $S$. aureus using vancomycin, daptomycin or penicillin improved the survival of the wax moth larvae in a dose dependent manner. ${ }^{138}$ The doses administered to the infected $G$. mellonella that were most effective, were similar to those recommended for use in humans. An investigation into the toxicity of $\mathrm{Cu}(\mathrm{II})$ and $\mathrm{Ag}(\mathrm{I})$ complexes by McCann et al. have demonstrated that the level of toxicity exhibited by the test compounds in G. mellonella was similar to that observed in Swiss mice. ${ }^{141}$ Although the use of mammals as in vivo models for testing new drug candidates is necessary, $G$. mellonella can be used as a good preliminary in vivo toxicity model. On average, only 500 compounds out of 10,000 compounds synthesised will reach animal testing, with only 10 reaching phase one clinical trials. ${ }^{140}$ The use of insects allows for the early optimisation of compounds that exhibit therapeutic potential which in turn reduces the number of mammals used. Insect experiments may also be able to supply information relating to suitable dosages and drug metabolism. ${ }^{138,142}$

### 2.3.3.2 Examination of the in vivo Tolerance of 2.3 and 2.4 in G. mellonella

In an effort to further investigate the biological activity of compounds $\mathbf{2 . 3}$ and $\mathbf{2 . 4}$ (Figure 2.27), complexes which possessed good anti-cancer activity against a range of cell lines (section 2.1.2), in vivo toxicity studies were carried out as described in section 2.5 . 1 using the larvae of the greater wax moth, G. mellonella. G. mellonella live in beehives in which the larvae feed on honeycomb and undergo metamorphosis to become a grey moth. Working with $G$. mellonella is quite easy. As shown in Figure 2.28, test compounds can be
administered into the haemocoel (body cavity) via injection into the last left pro-leg. By applying gentle pressure to the sides of the leg, the base of the pro-leg opens and will reseal once the syringe needle has been removed, without leaving a scar. The toxicity of a given compound is determined by calculating the percentage of $G$. mellonella larvae that survive over a 72 h period. The larvae are monitored every 24 h and death is assessed based on a lack of movement in response to stimulation together with discolouration of the cuticle (melanisation) (Figure 2.29).

Figure 2.27: $\mathrm{Cu}(\mathrm{II})$ complexes which were synthesised previously in the McGinley group and showed good anti-cancer activity.

Figure 2.28: Compound administration to G. mellonella (reprinted with permission). ${ }^{143}$

Figure 2.29: Appearance of (a) healthy, living G. mellonella larvae and (b) dead G. mellonella larvae. Pictures reprinted with permission.

The results of the treatment of $G$. mellonella with $\mathbf{2 . 3}$ and $\mathbf{2 . 4}$ are presented in Figure 2.30 as the survival of $G$. mellonella larvae (expressed as \%) as a function of the compound
dosages administered. As can be seen from Figure 2.30, at concentrations of 1-100 $\mu \mathrm{g} / \mathrm{mL}$ the minimum survival rate of $73 \%$ was observed for compound 2.3 , with a $87 \%$ survival rate seen for the highest dose of $100 \mu \mathrm{~g} / \mathrm{mL}$. For compound 2.4 , which was the most active against cancer cell lines, the survival rate was observed to decrease to $\sim 53 \%$ on going to a dosage concentration of $100 \mu \mathrm{~g} / \mathrm{mL}$. It was also apparent that larvae death occurred within the first 24 h post injection, with no further decrease in survival rate observed thereafter.

The similarities between the mammalian and insect innate immune systems have allowed insects to be used as models for a variety of in vivo studies including microbe virulence, drug efficacy and the toxicity and metabolism of drug candidates. ${ }^{137,138,142,144}$ Considering the positive correlation that has been observed between compound toxicity in $G$. mellonella and mice, the results presented here prove encouraging and suggest that they could have applications as low toxicity anti-cancer therapeutic agents.

Figure 2.30: Survival of G. mellonella larvae (expressed as \%) post injection at 24, 48 and 72 h .2 .3 (top graph) displayed low toxicity over incubation time of 72 h .2 .4 (bottom) showed a decrease in survival rates at higher concentrations within 24 h incubation time.

### 2.4 Conclusions

Herein, the synthesis of a pyridyl tetrazole metal complex library was undertaken with the aim of carrying these compounds forward to anti-cancer testing and SAR screening. The structure of each ligand synthesised was elucidated by means of HRMS, ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR and IR spectroscopies. Metal complexes synthesised were characterised by IR, UV-Vis spectroscopies, elemental analysis, magnetic moment and in some cases X-ray crystallography.

Synthesis of the ligands involved formation of the tetrazole ring followed by alkylation at the $\mathrm{N}-1$ or $\mathrm{N}-2$ position of the tautomeric tetrazole ring. It was found that the $\mathrm{N}-2$ regioisomer was always the major regioisomer formed, although regioselectivity was never pronounced. The only significant regioselectivity achieved was in the reaction of 1,3-dibromopropane and $\mathbf{2 . 5}$, where the $\mathrm{N}-2$ isomer was formed in a clear majority as a ratio of $10: 33$ was observed for the $\mathrm{N}-1$ and $\mathrm{N}-2$ isomers respectively.

Synthesis of the metal complexes involved heating a solution of the appropriate metal salt and ligand in MeOH for 2 hours. All reactions with $\mathrm{MCl}_{2}$ salts were proposed to have resulted in the formation dichloro-bridged dimers, which were analogous to complexes studied previously in the McGinley group. All $\mathrm{Co}(\mathrm{SCN})_{2}$ complexes formed octahedral complexes which were also similar to compounds studied previously. $\mathrm{ZnCl}_{2}$ failed to complex to the alcohol chain derivatives in MeOH , perhaps due to a combination of poor solubility of the ligands and labile coordination bonds to the $\mathrm{d}^{10}$ ion. Alternative solvent systems could alleviate this issue.

Future work will involve an investigation into the anti-cancer activities of the complexes synthesised. This work will be carried out in the US National Cancer Institute where compounds are tested against 60 human tumour cell lines for their anti-cancer capabilities. This screening programme is a rich source of information about the mechanisms of growth inhibition and tumour-cell kill and has contributed significantly to the area of cancer chemotherapy. ${ }^{145}$

### 2.5 Experimental

### 2.5.1 Instrumentation

${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR ( $\delta \mathrm{ppm}$; $J \mathrm{~Hz}$ ) spectra were recorded on a Bruker Avance 300 MHz NMR spectrometer using saturated $\mathrm{CDCl}_{3}$ or $d_{6}$-DMSO solutions with a $\mathrm{SiMe}_{4}$ reference, with resolutions of 0.18 Hz and 0.01 ppm , respectively. Infrared spectra ( $\mathrm{cm}^{-1}$ ) were recorded as KBr discs or liquid films on NaCl plates using a Perkin Elmer System 2000 FT-IR spectrometer. Solution UV-Vis spectra were recorded using a Unicam UV 540 spectrometer. Melting point analyses were carried out using a Stewart Scientific SMP 1 melting point apparatus and are uncorrected. Electrospray (ESI) mass spectra were collected on an Agilent Technologies 6410 Time of Flight LC/MS. Compounds were dissolved in acetonitrile-water (1:1) solutions containing $0.1 \%$ formic acid, unless otherwise stated. The interpretation of mass spectra was made using "Agilent Masshunter Workstation Software". Magnetic susceptibility measurements were carried out at room temperature using a Johnson Matthey Magnetic Susceptibility Balance with $\left[\mathrm{HgCo}(\mathrm{SCN})_{4}\right]$ as reference. Microanalyses were carried out at the Microanalytical Laboratory of the National University of Ireland Maynooth using a Thermo Finnigan Elementary Analyzer Flash EA 1112. The results were analysed using the Eager 300 software. All crystal structures resulting from this work were solved by Dr. John Gallagher (Dublin City University) using an Oxford Diffraction Gemini-S Ultra diffractometer. Structures were solved using the sHELxs97 direct methods program. Molecular diagrams were generated using Mercury software. Starting materials were commercially obtained and used without further purification. Solvents used were of HPLC grade. G. mellonella in the sixth developmental stage were obtained from The Mealworm Company (Sheffield, England) and stored in wood shavings in the dark at $15^{\circ} \mathrm{C}$. Experiments were personally carried out using ten healthy G. mellonella (between $0.20-0.30 \mathrm{~g}$ in weight) placed in sterile, 9 cm petri dishes, containing a sheet of Whatmann filter paper and wood shavings. Test compound solutions were made on the day prior to administration. Each compound was dissolved in DMSO and added to sterile, distilled water to give stock solutions of 0.05\% (v/v) DMSO. Using a $300 \mu \mathrm{~L}$ Thermo Myjector syringe (29G), sterile test solutions ( $20 \mu \mathrm{~L}$ ) were administered to the larvae by injection. Injections were made into the last, left pro-leg of the $G$. mellonella larvae, directly into the haemocoel. Larvae were then incubated at $37^{\circ} \mathrm{C}$. Caution! Nitrogen-rich compounds such as tetrazole derivatives are used as components for explosive mixtures. In our laboratory, the reactions described were run on a few gram scale, and no problems were encountered. However, great caution should be exercised when heating or handling compounds of this type.

### 2.5.2 Synthesis of Alkylbromo Pyridyl Tetrazoles

### 2.5.2.1 Synthesis of 2-(2H-tetrazol-5-yl)pyridine (2.5)

A suspension of 2-cyanopyridine ( $2.00 \mathrm{~g}, 19 \mathrm{mmol}$ ), $\mathrm{NaN}_{3}(2.81 \mathrm{~g}, 43 \mathrm{mmol}), \mathrm{NH}_{4} \mathrm{Cl}(2.32 \mathrm{~g}$, 43 mmol ) and $\mathrm{LiCl}(5.71 \mathrm{~g}, 134 \mathrm{mmol})$ in anhydrous DMF ( 40 mL ) was stirred for 10 h at $110^{\circ} \mathrm{C}$. After this time, the solution was cooled and the insoluble salts were removed by filtration. The solvent was then evaporated under reduced pressure and the residue was dissolved in deionised $\mathrm{H}_{2} \mathrm{O}(200 \mathrm{~mL})$ and acidified with concentrated $\mathrm{HCl}(3 \mathrm{~mL})$ to initiate precipitation. The product was removed by filtration, washed with $\mathrm{H}_{2} \mathrm{O}(3 \times 40 \mathrm{~mL})$ and dried. The white solid was recrystallised from hot EtOH to yield 2.5 as white needles ( 2.72 g, $96 \%$ ). m.p. $221-223^{\circ} \mathrm{C}\left(\mathrm{lit} .211^{\circ} \mathrm{C}\right.$ ). ${ }^{30} \mathrm{IR}(\mathrm{KBr}): ~ v=2669,1638,1621,1541,1488,1459$, 1382, 1287, 1229, 1098, 1043, 1016, 976, 800, $755 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO): $\delta=8.79-$ 8.81 (m, 1 H, pyr-H), 8.22-8.24 (m, 1 H, pyr-H), 8.06-8.11 (m, 1 H, pyr-H), 7.61-7.66 (m, 1 H, pyr-H) ppm. ${ }^{13} \mathrm{C}$ NMR ( $d_{6}$-DMSO): $\delta=154.9\left(\mathrm{CN}_{4}\right), 150.0,143.8138 .1,125.9,122.5 \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{~N}_{5}[\mathrm{M}+\mathrm{H}]^{+} 148.0618$, found 148.0624 .

NMR data are in agreement with literature values. ${ }^{30}$

### 2.5.2.2 Synthesis of Alkylbromo Pyridyl Tetrazoles

The general procedure for the synthesis of 2.1, 2.2 and $\mathbf{2 . 6} \mathbf{- 2 . 2 5}$ was as follows. To $\mathbf{2 . 5}$ ( $1.00 \mathrm{~g}, 7 \mathrm{mmol}$ ) suspended in MeCN was added $\mathrm{K}_{2} \mathrm{CO}_{3}(9.38 \mathrm{~g}, 68 \mathrm{mmol})$. The resulting solution was heated to reflux for 30 min and to the hot solution was added $1, \mathrm{n}$ dibromoalkane ( 24 mmol ) ( $\mathrm{n}=3,4,6,8$ ). The reaction mixture was then stirred at reflux temperature for a further 24 h . After cooling the supension was filtered and the filtrate was concentrated under reduced pressure to afford an oil, which was purified by column chromatography on silica gel (Pet. Ether:EtOAc, 2:1). This yielded two isomeric products.

### 2.5.2.2.1 2-(1-(3-bromopropyl)-1H-tetrazol-5-yl)pyridine (2.6)

Dark brown solid ( $0.46 \mathrm{~g}, 13 \%$ ). m.p. 190-192 ${ }^{\circ} \mathrm{C}$. IR (KBr): $v=2980,2909,1624,1586$, 1502, 1447, 1374, 1301, 1166, 1140, 971, 799, $720 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta=8.73-8.76$ (m, 1 H, pyr-H), 8.36-8.39 (m, 1 H, pyr-H), 7.89-7.95 (m, 1 H, pyr-H), 7.44-7.49 (m, 1 H, pyr-H), $5.15\left(\mathrm{t}, 2 \mathrm{H}, \mathrm{J}=6.8 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{~N}\right), 3.47\left(\mathrm{t}, 2 \mathrm{H}, \mathrm{J}=6.4 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{Br}\right), 2.53-2.62\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{2}\right)$ ppm. ${ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=151.8\left(\mathrm{CN}_{4}\right), 149.5,144.7,137.5,125.4,124.5,48.2\left(\mathrm{CH}_{2} \mathrm{~N}\right), 34.8$ ( $\mathrm{CH}_{2} \mathrm{Br}$ ), 31.1 ppm. ESI-HRMS: calcd. for $\mathrm{C}_{9} \mathrm{H}_{11} \mathrm{~N}_{5} \mathrm{Br}[\mathrm{M}+\mathrm{H}]^{+} 268.0192$, found 268.0188 .

### 2.5.2.2.2 2-(2-(3-bromopropyl)-2H-tetrazol-5-yl)pyridine (2.7)

Waxy orange solid ( $1.38 \mathrm{~g}, 38 \%$ ). m.p. $158-160^{\circ} \mathrm{C}$. IR ( KBr ): $v=2980,2931,1623,1589$, 1533, 1469, 1432, 1357, 1283, 1119, 1042, 993, 799, $740 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.78-$ 8.79 (m, 1 H, pyr-H), 8.24-8.27 (m, 1 H, pyr-H), 7.82-7.90 (m, 1 H, pyr-H), 7.36-7.43 (m, 1 H, pyr-H), $4.91\left(\mathrm{t}, 2 \mathrm{H}, J=6.7 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{~N}\right.$ ), $3.46\left(\mathrm{t}, 2 \mathrm{H}, J=6.2 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{Br}\right), 2.62-2.71(\mathrm{~m}, 2 \mathrm{H}$, $\left.\mathrm{CH}_{2}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=164.9\left(\mathrm{CN}_{4}\right), 150.3,146.6,137.4,124.9,122.4,51.5\left(\mathrm{CH}_{2} \mathrm{~N}\right)$, $31.8\left(\mathrm{CH}_{2} \mathrm{Br}\right), 28.7 \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{9} \mathrm{H}_{11} \mathrm{~N}_{5} \mathrm{Br}[\mathrm{M}+\mathrm{H}]^{+}$268.0192, found 268.0205.

### 2.5.2.2.3 2-(1-(4-bromobutyl)-1H-tetrazol-5-yl)pyridine (2.8)

Waxy brown solid ( $0.86 \mathrm{~g}, 23 \%$ ). m.p. $41-45^{\circ} \mathrm{C}$. IR ( KBr ): $v=2958,2865,1590,1530$, 1471, 1432, 1403, 1330, 1277, 1122, 1092, 993, 796, $742 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.73-$ 8.75 (m, 1 H, pyr-H), 8.36-8.38 (m, 1 H, pyr-H), 7.90-7.95 (m, 1 H, pyr-H), 7.45-7.49 (m, 1 H, pyr-H), $5.04\left(\mathrm{t}, 2 \mathrm{H}, J=7.0 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{~N}\right.$ ), $3.44\left(\mathrm{t}, 2 \mathrm{H}, J=6.2 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{Br}\right)$, 2.12-2.22 (m, 2 H , $\mathrm{CH}_{2}$ ), 1.89-1.97 (m, $2 \mathrm{H}, \mathrm{CH}_{2}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta=151.7\left(\mathrm{CN}_{4}\right), 149.5,144.9,137.5$, 125.3, 124.6, $48.6\left(\mathrm{CH}_{2} \mathrm{~N}\right), 32.5\left(\mathrm{CH}_{2} \mathrm{Br}\right), 30.9,29.2$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{10} \mathrm{H}_{13} \mathrm{~N}_{5} \mathrm{Br}$ $[\mathrm{M}+\mathrm{H}]^{+} 282.0349$, found 282.0352 .

### 2.5.2.2.4 2-(2-(4-bromobutyl)-2H-tetrazol-5-yl)pyridine (2.9)

Waxy brown solid ( $0.62 \mathrm{~g}, 16 \%$ ). m.p. $34-36{ }^{\circ} \mathrm{C}$. IR ( KBr ): $v=2942,2866,1624,1586$, 1456, 1434, 1350, 1292, 1164, 1050, 1010, $792,750 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.78-8.80$ ( $\mathrm{m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}$ ), 8.24-8.27 (m, 1 H, pyr-H), 7.84-7.90 (m, $1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}$ ), 7.38-7.43 (m, 1 H , pyr-H), $4.77\left(\mathrm{t}, 2 \mathrm{H}, J=6.8 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{~N}\right), 3.44\left(\mathrm{t}, 2 \mathrm{H}, J=6.4 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{Br}\right), 2.24-2.34(\mathrm{~m}, 2 \mathrm{H}$, $\mathrm{CH}_{2}$ ), 1.89-1.98 (m, $2 \mathrm{H}, \mathrm{CH}_{2}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=164.9\left(\mathrm{CN}_{4}\right), 150.3,146.8,137.1$, 124.8, 122.4, $52.4\left(\mathrm{CH}_{2} \mathrm{~N}\right), 32.1\left(\mathrm{CH}_{2} \mathrm{Br}\right), 29.2,27.8 \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{10} \mathrm{H}_{13} \mathrm{~N}_{5} \mathrm{Br}$ $[\mathrm{M}+\mathrm{H}]^{+} 282.0349$, found 282.0350 .

### 2.5.2.2.5 2-(1-(8-bromooctyl)-1H-tetrazol-5-yl)pyridine (2.10)

Waxy orange solid ( $0.77 \mathrm{~g}, 17 \%$ ). m.p. $41-44^{\circ} \mathrm{C}$. IR ( KBr ): $v=2937,2860,1613,1593$, 1467, 1433, 1417, 1354, 1150, 1091, 1043, 991, 803, $747 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.71-$ $8.74(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 8.35-8.38(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 7.87-7.93(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 7.42-7.47(\mathrm{~m}, 1$ H, pyr-H), $4.98\left(\mathrm{t}, 2 \mathrm{H}, J=7.2 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{~N}\right), 3.39\left(\mathrm{t}, 2 \mathrm{H}, J=6.9 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{Br}\right), 1.91-2.00(\mathrm{~m}, 2 \mathrm{H}$, $\mathrm{CH}_{2}$ ), 1.78-1.87 (m, $2 \mathrm{H}, \mathrm{CH}_{2}$ ), 1.30-1.38 (m, $8 \mathrm{H}, \mathrm{CH}_{2}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta=151.5$ $\left(\mathrm{CN}_{4}\right), 149.4,145.1$ 137.4, 125.2, 124.6, $49.5\left(\mathrm{CH}_{2} \mathrm{~N}\right), 33.9\left(\mathrm{CH}_{2} \mathrm{Br}\right), 32.9,29.8,28.7,28.4$, 27.9, 26.1 ppm. ESI-HRMS: calcd. for $\mathrm{C}_{14} \mathrm{H}_{21} \mathrm{~N}_{5} \mathrm{Br}[\mathrm{M}+\mathrm{H}]^{+} 338.0975$, found 338.0983 .

### 2.5.3 Metal Complexation Reactions with Alkylbromo Pyridyl Tetrazoles

### 2.5.3.1 General Procedure for Metal Complexation Reactions

0.20 g of ligand was dissolved in $\mathrm{MeOH}(20 \mathrm{~mL})$. To this solution was added 1 equivalent of metal salt $\left(\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}, \mathrm{NiCl}_{2} .6 \mathrm{H}_{2} \mathrm{O}, \mathrm{Co}(\mathrm{SCN})_{2}\right.$ or $\left.\mathrm{ZnCl}_{2}\right)$ in $\mathrm{MeOH}(20 \mathrm{~mL})$. The resulting solution was heated to reflux under nitrogen for 2 hours. The solution was then cooled to room temperature and allowed to stand for several days. The resulting solids were then isolated by filtration and washed with MeOH .

### 2.5.3.1.1 $\left[\mathrm{Cu}(2.6) \mathrm{Cl}_{2}\right]_{2}(2.26)$

Green solid ( $0.12 \mathrm{~g}, 40 \%$ ). $\mathrm{C}_{18} \mathrm{H}_{20} \mathrm{Br}_{2} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10}$ : calcd. ### 2.5.4.1.5 2-(1-octyl-1H-tetrazol-5-yl)pyridine (2.16)

Brown oil (0.82 g, 23\%). IR (neat): $v=2956,2927,2856,1591,1467,1433,1377,1120$, 1036, 797, 743, $730 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.71-8.74(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 8.34-8.38(\mathrm{~m}, 1$ H, pyr-H), 7.87-7.93 (m, 1 H, pyr-H), 7.42-7.47 (m, $1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 4.97(\mathrm{t}, 2 \mathrm{H}, J=7.3 \mathrm{~Hz}$, $\mathrm{CH}_{2} \mathrm{~N}$ ), 1.83-1.97 (m, $2 \mathrm{H}, \mathrm{CH}_{2}$ ), 1.25-1.30(m, $\left.10 \mathrm{H}, \mathrm{CH}_{2}\right), 0.86\left(\mathrm{t}, 3 \mathrm{H}, J=6.9 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm}$.
${ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=151.6\left(\mathrm{CN}_{4}\right), 149.4,145.1,137.3,125.2,124.5,49.6\left(\mathrm{CH}_{2} \mathrm{~N}\right), 31.7$, 29.8, 29.1, 28.9, 26.2, 22.5, 14.0 ppm. ESI-HRMS: calcd. for $\mathrm{C}_{14} \mathrm{H}_{22} \mathrm{~N}_{5}[\mathrm{M}+\mathrm{H}]^{+} 260.1870$, found 260.1881 .

### 2.5.4.1.6 2-(2-octyl-2H-tetrazol-5-yl)pyridine (2.17)

Yellow oil ( $0.76 \mathrm{~g}, 22 \%$ ). IR (neat): $v=2985,2927,2856,1593,1571,1522,1466,1432$, 1419, 1386, 1356, 1158, 1043, 1015, 803, 746, $726 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta=8.77-8.79$ ( $\mathrm{m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}$ ), 8.23-8.27 (m, 1 H, pyr-H), 7.83-7.89 (m, $1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}$ ), 7.37-7.41 (m, 1 H , pyr-H), $4.70\left(\mathrm{t}, 2 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{~N}\right.$ ), 2.07-2.12 (m, $2 \mathrm{H}, \mathrm{CH}_{2}$ ), 1.23-1.34 (m, $10 \mathrm{H}, \mathrm{CH}_{2}$ ), $0.86\left(\mathrm{t}, 3 \mathrm{H}, J=6.9 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=164.7\left(\mathrm{CN}_{4}\right), 150.3,146.9,137.0$, 124.7, 122.3, $53.5\left(\mathrm{CH}_{2} \mathrm{~N}\right), 31.6,29.3,28.9,28.826 .2,22.5,14.0 \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{14} \mathrm{H}_{21} \mathrm{~N}_{5}[\mathrm{M}+\mathrm{Na}]^{+} 282.1689$, found 282.1699 .

### 2.5.5 Metal Complexation Reactions with Alkyl Pyridyl Tetrazoles

### 2.5.5.1 General Procedure for Metal Complexation Reactions

The attainment of metal complexes was achieved using the same methods utilised in section 2.5.3.

### 2.5.5.1.1 $\quad\left[\mathrm{Cu}(2.12) \mathrm{Cl}_{2}\right]_{2}(2.54)$

Green solid ( $0.17 \mathrm{~g}, 51 \%$ ). $\mathrm{C}_{20} \mathrm{H}_{26} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10}$ : calcd. C 35.57 , H 3.88, N $20.74 \%$; found C 35.39, H 3.92, N 20.27\%. IR (KBr): $v=2961,2868,1614,1546,1482,1457,1437,1378$, 1251, 1166, 1049, 1003, $719 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 836 \mathrm{~nm}, \varepsilon=110 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.06 B.M.

### 2.5.5.1.2 $\quad\left[\mathrm{Cu}(2.13) \mathrm{Cl}_{2}\right]_{2}(2.55)$

Green solid ( $0.12 \mathrm{~g}, 36 \%$ ). $\mathrm{C}_{20} \mathrm{H}_{26} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10}$ : calcd. C 35.57 , H 3.88, $\mathrm{N} 20.74 \%$; found C 35.63, H 4.05, N 20.45\%. IR (KBr): $v=2961,2880,1619,1609,1552,1461,1449,1352$, 1269, 1100, 1026, 799, 758, $724 \mathrm{~cm}^{-1}$. $\lambda_{\max }(\mathrm{MeOH}) 808 \mathrm{~nm}, \varepsilon=115 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 1.98 B.M.

### 2.5.5.1.3 $\quad\left[\mathrm{Cu}(2.14) \mathrm{Cl}_{2}\right]_{2}(2.56)$

Green solid ( $0.11 \mathrm{~g}, 35 \%$ ). $\mathrm{C}_{24} \mathrm{H}_{34} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10}$ : calcd. C 39.41, H 4.68, N 19.15\%; found C 39.23, H 4.75, N 18.66\%. IR (KBr): $v=2955,2927,2872,1611,1541,1482,1455,1382$, 1112, 1050, 1008, 792, 751, $719 \mathrm{~cm}^{-1}$. $\lambda_{\max }(\mathrm{MeOH}) 840 \mathrm{~nm}, \varepsilon=111 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.00 B.M.

### 2.5.5.1.4 $\quad\left[\mathrm{Cu}(2.15) \mathrm{Cl}_{2}\right]_{2}(2.57)$

Green solid ( $0.12 \mathrm{~g}, 38 \%$ ). $\mathrm{C}_{24} \mathrm{H}_{34} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10}$ : calcd. C 39.41, H 4.68, $\mathrm{N} 19.15 \%$; found C 39.20, H 4.76, N 18.87\%. IR (KBr): $v=2953,2925,2858,1617,1551,1450,1354,1284$, $1103,1025,801,757,726 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 812 \mathrm{~nm}, \varepsilon=129 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.04 B.M.

### 2.5.5.1.5 $\quad\left[\mathrm{Cu}(2.16) \mathrm{Cl}_{2}\right]_{2}(2.58)$

Green solid ( $0.13 \mathrm{~g}, 43 \%$ ). $\mathrm{C}_{28} \mathrm{H}_{42} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10}$ : calcd. C 42.70, H 5.37, $\mathrm{N} 17.78 \%$; found C 41.66, H 5.39, N 17.53\%. IR (KBr): $v=2955,2924,2857,1611,1540,1482,1446,1384$, 1113, 1049, 1007, 792, 748, $719 \mathrm{~cm}^{-1}$. $\lambda_{\max }(\mathrm{MeOH}) 832 \mathrm{~nm}, \varepsilon=114 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 1.81 B.M.

### 2.5.5.1.6 $\quad\left[\mathrm{Cu}(2.17) \mathrm{Cl}_{2}\right]_{2}(2.59)$

Green solid ( 0.10 g, $33 \%$ ). $\mathrm{C}_{28} \mathrm{H}_{42} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10}$ : calcd. C 42.70, H 5.37, $\mathrm{N} 17.78 \%$; found C 43.61, H 5.39, N 17.24\%. IR (KBr): $v=2955,2923,2850,1616,1537,1466,1454,1432$, 1360, 1285, 1158, 1014, 801, 765, $726 \mathrm{~cm}^{-1}$. $\lambda_{\max }(\mathrm{MeOH}) 812 \mathrm{~nm}, \varepsilon=86 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.18 B.M.

### 2.5.5.1.7 $\quad\left[\mathrm{Ni}(2.12) \mathrm{Cl}_{2}\right]_{2}(2.60)$

Green solid ( 0.29 g, 80\%). $\mathrm{C}_{20} \mathrm{H}_{26} \mathrm{Cl}_{4} \mathrm{~N}_{10} \mathrm{Ni}_{2} .4 \mathrm{H}_{2} \mathrm{O}$ : calcd. ### 2.5.6 Synthesis of Alcohol Pyridyl Tetrazoles

### 2.5.6.1 Synthesis of Ligands

Access to alkyl alcohol functionalised pyridyl tetrazoles was achieved through similar methods outlined in 2.5.2. Column chromatography was carried out using DCM:EtOAc (1:1) as the mobile phase. The alkylating agents used were 3-bromo-1-propanol, 4-bromo-1-butanol, 6-bromo-1-hexanol or 8-bromo-1-octanol.

### 2.5.6.1.1 3-(5-(pyridin-2-yl)-1H-tetrazol-1-yl)propan-1-ol (2.18)

### 2.5.7 Metal Complexation Reactions with Alcohol Pyridyl Tetrazoles

### 2.5.7.1 General Procedure for Metal Complexation Reactions

Metal complexes of alcohol functionalised pyridyl tetrazoles were synthesised using the methods outlined in section 2.5.3, unless otherwise stated.

### 2.5.7.1.1 $\quad\left[\mathrm{Cu}(2.18) \mathrm{Cl}_{2}\right]_{2}(2.78)$

Green solid ( $0.10 \mathrm{~g}, 61 \%$ ). $\mathrm{C}_{18} \mathrm{H}_{22} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{2}$ : calcd. C $31.81, \mathrm{H} 3.26, \mathrm{~N} 20.62 \%$; found C 32.11, H 3.06, N 20.55\%. IR (KBr): $v=3466,2933,1613,1551,1484,1455,1384,1283$,

1250, 1163, 1113, 1046, 1004, 799, $719 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 832 \mathrm{~nm}, \varepsilon=115 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.56 B.M.

### 2.5.7.1.2 $\quad\left[\mathrm{Cu}(2.19) \mathrm{Cl}_{2}\right]_{2}(2.79)$

Green solid ( $0.09 \mathrm{~g}, 55 \%$ ). $\mathrm{C}_{18} \mathrm{H}_{22} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{2}$ : calcd. C $31.81, \mathrm{H} 3.26, \mathrm{~N} 20.62 \%$; found C 32.18, H 3.13, N $20.36 \%$. IR (KBr): $v=3506,2930,2883,1618,1550,1459,1447,1395$, 1353, 1333, 1265, 1233, 1154, 1133, 1102, 1041, 1023, 999, 801, $761 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH})$ $844 \mathrm{~nm}, \varepsilon=147 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 1.82 B.M.

### 2.5.7.1.3 $\quad\left[\mathrm{Cu}(2.20) \mathrm{Cl}_{2}\right]_{2}(2.80)$

Carried out on a 0.03 g scale. Green solid ( $0.01 \mathrm{~g}, 20 \%$ ). $\mathrm{C}_{20} \mathrm{H}_{26} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{2}$ : calcd. C 33.96, H 3.70, N $19.80 \%$; found C 33.15, H 3.52, N 19.27\%. IR (KBr): $v=3431,3100,3070,3048$, $1614,1551,1481,1457,1382,1289,1112,1017,798,760 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 829 \mathrm{~nm}, \varepsilon=$ $112 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 1.81 B.M.

### 2.5.7.1.4 $\quad\left[\mathrm{Cu}(2.21) \mathrm{Cl}_{2}\right]_{2}(2.81)$

Carried out on a 0.09 g scale. Green solid ( $0.11 \mathrm{~g}, 75 \%$ ). $\mathrm{C}_{20} \mathrm{H}_{26} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{2}$ : calcd. C 33.96, H 3.70, N 19.80\%; found C 34.36, H 3.68, N 19.50\%. IR (KBr): $v=3512,3103,2960,2939$, $1614,1548,1484,1457,1434,1387,1293,1164,1111,1051,1034,1010,799 \mathrm{~cm}^{-1} . \lambda_{\max }$ (MeOH) $832 \mathrm{~nm}, \varepsilon=111 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 1.75 B.M.

### 2.5.7.1.5 $\quad\left[\mathrm{Cu}(2.22) \mathrm{Cl}_{2}\right]_{2}(2.82)$

Green solid ( $0.11 \mathrm{~g}, 73 \%$ ). $\mathrm{C}_{24} \mathrm{H}_{34} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{2}$ : calcd. C $37.75, \mathrm{H} 4.49, \mathrm{~N} 18.35 \%$; found C 38.10, H 4.42, $\mathrm{N} 17.89 \%$. IR (KBr): $v=3443,2928,2861,1615,1550,1484,1456,1173$, 1111, 1051, 1012, $796 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 840 \mathrm{~nm}, \varepsilon=105 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 1.79 B.M.

### 2.5.7.1.6 $\quad\left[\mathrm{Cu}(2.23) \mathrm{Cl}_{2}\right]_{2}(2.83)$

Green solid ( $0.10 \mathrm{~g}, 66 \%$ ). $\mathrm{C}_{24} \mathrm{H}_{34} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{2}$ : calcd. C $37.75, \mathrm{H} 4.49, \mathrm{~N} 18.35 \%$; found C 36.92, H 4.23, N 17.35\%. IR (KBr): $v=3449,2935,2860,1617,1554,1463,1454,1430$, 1286, 1160, 1072, 1045, 1020, 906, 802, 763, $725 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 816 \mathrm{~nm}, \varepsilon=136$ $\mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.14 B.M.

### 2.5.7.1.7 $\left[\mathrm{Cu}(2.24) \mathrm{Cl}_{2}\right]_{2}(2.84)$

Green solid ( 0.12 g, 80\%). $\mathrm{C}_{28} \mathrm{H}_{42} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{2}$ : calcd. C 41.03, H 5.17, N $17.09 \%$; found C 41.89, H 5.38, N 16.93\%. IR (KBr): $v=3429,2933,2913,2852,1615,1486,1458,1432$, $1052,1010,798,754 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 836 \mathrm{~nm}, \varepsilon=87 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.36 B.M.

### 2.5.7.1.8 $\quad\left[\mathrm{Cu}(2.25) \mathrm{Cl}_{2}\right]_{2}(2.85)$

Green solid ( 0.14 g , 93\%). $\mathrm{C}_{28} \mathrm{H}_{42} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{2}$ : calcd. C 41.03, H 5.17, $\mathrm{N} 17.09 \%$; found C 40.59, H 4.95, N 16.75\%. IR (KBr): $v=3451,2925,2854,1617,1553,1464,1453,1286$, 1160, 1072, 1010, 802, 763, $725 \mathrm{~cm}^{-1}$. $\lambda_{\max }(\mathrm{MeOH}) 808 \mathrm{~nm}, \varepsilon=121 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 1.81 B.M.

### 2.5.7.1.9 $\quad\left[\mathrm{Ni}(2.18) \mathrm{Cl}_{2}\right]_{2}(2.86)$

Green solid ( 0.16 g, 48\%). $\mathrm{C}_{18} \mathrm{H}_{22} \mathrm{Cl}_{4} \mathrm{Ni}_{2} \mathrm{~N}_{10} \mathrm{O}_{2}$ : calcd. C 32.27, H 3.31, N 20.92\%; found C 32.82, H 3.93, N 21.44\%. IR (KBr): $v=3379,1610,1540,1480,1461,1412,1299,1254$, $1160,1108,1049,1025,931,796,756,726,641,421 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 400 \mathrm{~nm}, \varepsilon=25$ $\mathrm{M}^{-1} \mathrm{~cm}^{-1} ; 676 \mathrm{~nm}, \varepsilon=9 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 4.36 B.M.

### 2.5.7.1.10 $\left[\mathrm{Ni}(2.19) \mathrm{Cl}_{2}\right]_{2}(2.87)$

Green solid ( 0.10 g , 31\%). $\mathrm{C}_{18} \mathrm{H}_{22} \mathrm{Cl}_{4} \mathrm{Ni}_{2} \mathrm{~N}_{10} \mathrm{O}_{2}$ : calcd. C 32.27, H 3.31, N 20.92\%; found C 32.23, H 3.85, N 19.97\%. Magnetic moment: 5.10 B.M.

## Chapter 3: Ester and Carboxylate Functionalised Pyridyl Tetrazoles

### 3.1 Introduction

### 3.1.1 Pyridyl Tetrazole Esters as Organic Linkers in Coordination Polymers

Thus far, a range of functionalised pyridyl tetrazole ligands were synthesised and their metal complexes isolated and characterised. Two ligands which were synthesised during the course of this work were of particular interest and hence are the focus of this chapter. The ligands in question (3.1 and 3.2) are shown in Figure 3.1. These ligands not only presented the typical binding pocket of the pyridine and tetrazole nitrogen atoms, but provided another binding site by virtue of the ester functionality.

3.1

3.2

Figure 3.1: Structures of the two ligands synthesised which provided an additional option for metal binding.

By incorporating both the pyridyl tetrazole nitrogen atoms and the ester oxygen atoms in complexation to the metal atom, there was potential for intermolecular interactions to form. This interaction could result in the formation of coordination polymers (CPs). As discussed in Chapter 1, CPs have attracted immense attention during the last two decades due to their potential applications. Since the structure of CPs have significant implications for their applications, the main goal in CP synthesis is to establish the synthesis conditions that lead to defined inorganic building blocks, without decomposition to the organic linker. ${ }^{96}$ Therefore, the knowledge of possible topologies, the functionality of organic linker molecules, as well as the understanding of typical metal coordination environments or the formation conditions of typical inorganic building blocks can help direct synthesis efforts. As of yet, however, it is still difficult to predict and control the structures of such complicated supramolecular assemblies. If CPs could indeed be formed from the employment of 3.1 and 3.2, an investigation into the synthesis conditions could be undertaken to gain an insight into how the regioisomerism and other variables affect the
final structures, thus contributing to the rapidly growing database of knowledge in this field.

### 3.1.2 Rationale for Employing 3.1 and 3.2 as Organic Linkers in CPs

Some of the most important characteristics of an organic compound used as a linker in CPs are their diverse coordination modes, molecular rigidity and flexibility. ${ }^{146}$ As regards diverse metal coordination modes, $\mathbf{3 . 1}$ and $\mathbf{3 . 2}$ offer a variety of possibilities. Tetrazoles and its derivatives have been employed extensively as multidentate chelating or bridging linkers because of their diverse connecting modes. ${ }^{146,147}$ Furthermore, tetrazole ligands can connect discrete or low-dimensional coordination motifs into higher-dimensional architectures via hydrogen bonds and $\pi-\pi$ interactions. ${ }^{148}$ It is also well known that pyridine ring N atoms have a good coordination capacity, hence the combination of both these heterocycles provides numerous opportunities for metal binding. Metal complexes with carboxylic esters have a long tradition in coordination chemistry, with coordination occurring with the carbonyl oxygen in the majority of cases. ${ }^{149}$ However, ester oxygens are generally rather weak bases except toward strong Lewis acids such as $\mathrm{BF}_{3} .{ }^{132}$ If this group did not interact with the metal centres, this lack of reactivity could be overcome by converting the ester group into an anionic carboxylate group (Figure 3.2). Carboxylate groups are hard bases and are generally more reactive towards metal coordination than ester oxygens.

3.1(pytza)

3.2(pytza)

Figure 3.2: The ethyl ester derivatives 3.1 and 3.2 could be converted to a carboxylate group, yielding 3.1(pytza) and $\mathbf{3 . 2}$ (pytza).

Carboxylate groups may coordinate to a metal ion in one of three modes: monodentate, chelating/bidentate or bridging (Figure 3.3). ${ }^{150}$ Furthermore, bridging carboxylates can coordinate to metals in a syn-syn, anti-anti and anti-syn configuration (Figure 3.4). ${ }^{132}$

(a)

(b)

(c)

Figure 3.3: The three different coordination modes that carboxylate ions can bind to metals: (a) monodentate; (b) chelating/bidentate; (c) bridging.

Figure 3.4: The most common forms of bridging carboxylates.

In addition, the anionic nature of the carboxylate linker negates the need for counteranions in the CP framework, and this increases the potential for porosity in the framework products. ${ }^{151}$ Therefore these ligands, which have mixed functionalities, could be excellent versatile building blocks, and the combination of these functionalities should allow the incorporation of interesting properties into the resulting networks.

Flexibility is also important in organic linkers in CPs. In these ligands, the oxygen containing functionality is connected to the tetrazole ring via a sp ${ }^{3} \mathrm{CH}_{2}$ moiety, which offers flexible orientations and conformational freedom which may provide more possibilities for the construction of CPs. Thus, due to the structural advantages of these type of ligands (Figure 3.5), their potential to be an organic linker is very promising. Despite this fact and that tetrazoles and its pyridyl and alkylated derivatives are easily accessed, there are limited examples of their use in CPs in the literature. More specifically, examples of the use of N -substituted tetrazoles in the synthesis of coordination networks are rare. ${ }^{152}$ The synthesis and use of tetrazolate-5-carboxylate ligands is becoming more common, however again reports in the literature are still sparse. ${ }^{153,154}$

Figure 3.5: The pyridyl tetrazole ligands synthesised in this work possess characteristics that are typical of organic linkers.

### 3.1.3 $\quad \mathrm{Bi}$ - and Multifunctional Tetrazole Based Ligands in CPs

CPs built up by carboxylate or tetrazolate ligands have been increasingly explored for their physical-chemical properties, such as molecular adsorption and recognition,155,156,157 magnetism, ${ }^{158}$ nonlinear optics, ${ }^{159}$ luminescence ${ }^{160}$ and energetic materials. ${ }^{161}$ Although there are limited reports of such ligands, the frequency of relevant examples being published has increased recently. These recent investigations into bifunctional tetrazolatecarboxylate ligands, especially the carboxylate 5 -substituted tetrazolates, is a consequence of their four N and two O donor atoms being potential binding centres. These features make them an excellent polydentate ligand. In 2010, Guo and co-workers employed the structurally related 1 H -tetrazolate- 5 -formic acid (3.3) and 1 H -tetrazolate- 5 -acetic acid (3.4) (Figure 3.6) in the assembly of $\mathrm{Zn}(\mathrm{II})$ and $\mathrm{Cd}(\mathrm{II})$ CPs in order to investigate the influence of ligand flexibility, secondary ligand and reaction conditions on the resulting structures. ${ }^{162,163}$ When comparing solvothermal reactions which only involved ligands $\mathbf{3 . 3}$ and 3.4 in the absence of a secondary ligand, they found that when using the more rigid ligand, 3.3, an isolated dinuclear structure formed. The lack of any significant intermolecular interactions was ascribed to the nature of the rigid ligand as well as the formation of the six-membered ring (Figure 3.6). On the other hand, when the more flexible 3.4 was employed in the reaction, a 3-D network resulted, with each ligand acting as a tetradentate linker to connect three $\mathrm{Zn}(\mathrm{II})$ atoms. These results showed that the bifunctional nature of the ligands played an important role in the attainment of CPs. Furthermore, these results show that flexibility is important in the formation of higher dimensional frameworks and that subtle structural changes to the ligand can govern the final structural topology.

Figure 3.6: Ligands with different flexibilities were used in the synthesis of coordination polymers. (a) Crystal structure of an isolated Zn (II) complex with 3.3 as the coordinating ligand; (b) crystal structure of a subunit of a Zn (II) framework with 3.4 as the coordinating ligand. ${ }^{163}$

An earlier report by Yuan et al. involved the in situ hydrolysis of tetrazole-5-ethyl acetate to the aforementioned $1 H$-tetrazolate- 5 -acetic acid (3.4) in aqueous NaOH solution under conventional reaction conditions. ${ }^{154}$ When $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}$ was added to this solution, blue crystals formed which on analysis by single crystal X-ray diffraction revealed a heterometallic 2-D network (Figure 3.7), demonstrating that these bifunctional ligands are versatile and adaptable for the coordination requirements of metal atoms. Heterometallic CPs are of great interest as the incorporation of two or more kinds of metal ions can add different functionalities which can be useful in the area of catalysis. ${ }^{164}$ The advantages of using bifunctional tetrazolate-carboxylate ligands in this context are recognisable, as the presence of different types of donor atoms can result in preferential coordination to different metal atoms.

Figure 3.7: Building unit of a Cu-Na coordination polymer. ${ }^{154}$

More recently, Lu et al. synthesised two novel 5-(pyrazinyl) tetrazolate CPs, 3.5 and 3.6, with 3.5 displaying strong luminescent properties suitable for green light luminescent materials. ${ }^{148}$ The presence of another aromatic nitrogen heterocycle along with the tetrazolate moiety was clearly advantageous in the attainment of $\mathbf{3 . 5}$ as the ligand acted as a tridentate chelating-bridging ligand, which linked neighbouring binuclear subunits to form an infinite chain (Figure 3.8). In 3.6, the ligand propagates a 1-D chain via simultaneous tridentate and bidentate chelating-bridging which further demonstrates the versatility of these type of bifunctional ligands and the advantages of installing another aromatic heterocycle.

In a rare example of an N -substituted tetrazole being employed in the synthesis of a $\mathrm{CP}, \mathrm{Li}$ and co-workers reported coordination networks dependent on the ligand 2-(5-(pyrazin-2-yl)-2H-tetrazol-2-yl) acetic acid (3.7, Figure 3.9). ${ }^{146}$ Reactions of $\mathrm{Cd}(\mathrm{II}), \mathrm{Co}(\mathrm{II}), \mathrm{Zn}(\mathrm{II})$, $\mathrm{Mn}(\mathrm{II})$ and $\mathrm{Ni}(\mathrm{II})$ salts with 3.7 in pH 6 solutions, either under solvothermal conditions or
at room temperature, yielded diverse 1-D and 2-D frameworks. This diversity is owing to the strong combined coordinative abilities of the flexible carboxylate groups, the tetrazole ring and the pyrazine ring which endows the ligand with an abundance of coordination modes. The coordination modes which were present in these frameworks are depicted in Figure 3.10. These results indicate that similar types of multifunctional ligands have great potential in the field of CP synthesis.

### 3.2 Aims and Objectives of Chapter

Although the above examples demonstrate that these type of bi- and multifunctional ligands have excellent potential to form coordination polymers, there are limited examples of similar compounds being exploited for this potential in the literature. For the purpose of our research, and the fact that our previously synthesised ligands bear a resemblance to the above examples, we aimed to investigate multifunctional ligands with a pyridyl tetrazole scaffold for their potential use in the synthesis of high dimensional coordination polymers. We envisaged the use of ethyl acetate N -functionalised pyridyl tetrazoles as organic linkers in the framework syntheses, however the ester functionality could easily be converted to a carboxylic acid if desired. Different metal ions would also be utilised, which would allow an analysis of the influence of metal ion radii on the resulting architectures. The effect of the position of the ester arm on the structures would also be examined. Coordination polymers derived from different ligands are referred to as "ligand-originated isomers". ${ }^{165}$ Although many different ligands have been investigated for coordination polymer formation, there are few examples of any systematic studies of ligand-originated isomers that arise from differences in regiochemical isomerism in a multifunctional ligand. Hence, these investigations would represent a rare study in this area. Finally, examination of the products by EPR spectroscopy and solid state luminescence was also intended, the concepts of which are also introduced in this chapter.

### 3.3 Results and Discussion

### 3.3.1 Synthesis of the Pyridyl Tetrazole Ester Derivatives

Access to the ester functionalised pyridyl tetrazoles was achieved through the alkylation of 2.5 in the presence of $\mathrm{K}_{2} \mathrm{CO}_{3}$ and ethyl bromoacetate (Scheme 3.1).

Scheme 3.1: Alkylation of $\mathbf{2 . 5}$ yielded two regioisomers $\mathbf{3 . 1}$ and 3.2. Reagents and conditions: (i) $\mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{BrCH}_{2} \mathrm{COOEt}, \mathrm{CH}_{3} \mathrm{CN}, \Delta, 24 \mathrm{~h}$.
${ }^{1} \mathrm{H}$ NMR spectroscopy was carried out on the crude residue obtained after filtration and evaporation of the filtrate. It was evident from the ${ }^{1} \mathrm{H}$ NMR spectrum that a mixture of regioisomers were present, as there were double the number of expected peaks observed (Figure 3.11). No significant regioselectivity was observed with the N-1 and N-2 regioisomers being present in a 10:9 ratio. Thin Layer Chromatography using EtOAc and Pet. Ether as the mobile phase showed that the two isomers had very different $R_{f}$ values. Therefore column chromatography was employed to separate the two isomers. The two isolated isomers were again analysed by NMR spectroscopy and it was deduced from the spectra that the isomer with the highest $R_{f}$ value ( 0.58 ) was the $\mathrm{N}-1$ isomer and the $\mathrm{N}-2$ isomer had the lower $\mathrm{R}_{\mathrm{f}}$ value ( 0.28 ). The ${ }^{1} \mathrm{H}$ NMR spectra of the regioisomers, which can be seen in Figure 3.11, exhibited four multiplets in the aromatic region ( $7.42-8.79 \mathrm{ppm}$ ) which were attributed to the pyridyl protons; a singlet which integrated for two protons was observed at 5.74 ppm for the $\mathrm{N}-1$ regioisomer and 5.50 ppm for the $\mathrm{N}-2$ regioisomer which arose due to the $\mathrm{CH}_{2}$-tet protons of the ethyl acetate moiety; the $\mathrm{CH}_{2}$ protons of the ethoxy group gave rise to a quartet at $\sim 4.20 \mathrm{ppm}$ and the $\mathrm{CH}_{3}$ protons of the ethoxy group appeared at $\sim 1.20 \mathrm{ppm}$ as a triplet. In the ${ }^{13} \mathrm{C}$ NMR spectra of the isomers, the C-5 of the tetrazole ring gave rise to a signal at 152.1 ppm for the $\mathrm{N}-1$ regioisomer and 164.8 ppm for the $\mathrm{N}-2$ regioisomer. The presence of a carbonyl carbon was implied by resonances observed at 165.9 and 165.2 ppm for the $\mathrm{N}-1$ and $\mathrm{N}-2$ regioisomers respectively. Further confirmation that the ester group was present in the compounds was attained on
examination of the IR spectra of the isomers, with a $v(\mathrm{C}=0)$ stretch observed at $\sim 1746$ $\mathrm{cm}^{-1}$.

Figure 3.11: ${ }^{1} \mathrm{H}$ NMR spectra of crude mixture of $\mathbf{3 . 1}$ and $\mathbf{3 . 2}$ (red), purified $\mathbf{3 . 1}$ (green) and purified 3.2 (blue), which were all obtained in $\mathrm{CDCl}_{3}$.

Single crystals were obtained for compound 3.1 and were analysed by X-ray crystallography. The results of this analysis are presented in Figure 3.12 and reveal that the pyridine and tetrazole rings are almost co-planar with respect to each other, with the ester pendant arm appearing not to have a pronounced effect on the co-planarity. The methylene group connecting the ester moiety to the tetrazole ring allows the group to orientate itself out of the plane of the heterocyclic systems, being at an angle of 71.1(4) ${ }^{\circ}$ to the two heterocyclic ring systems.

Figure 3.12: Crystal structures of 3.1. Figure on right demonstrates the non co-planar nature of the ester arm with respect to the pyridyl tetrazole rings. Blue $=$ nitrogen, red $=$ oxygen, grey = carbon, green = hydrogen.

### 3.3.2 Metal Complexation Reactions

### 3.3.2.1 Metal Complexation with Pyridyl Tetrazole Ester Derivatives

Metal complexation reactions were carried out in a 1:1 metal to ligand stoichiometric ratio in MeOH . After 2 h at reflux temperature, the reaction solutions were cooled to room temperature and allowed to stand for several days. The resulting solids were then filtered off.

The product from the reaction of 3.1 with $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}$ was a green crystalline solid. In order to determine if the ester group was coordinating to the $\mathrm{Cu}(\mathrm{II})$ atom, IR spectroscopy was undertaken. If the ester group was coordinated to the metal centre, a significant decrease of the $v(\mathrm{C}=0)$ frequency would be expected (with shifts of $50-150 \mathrm{~cm}^{-1}$ ) and an increase of the $v(\mathrm{C}-0)$ vibration would also be observed. ${ }^{166}$ The IR spectrum of the complex showed no such significant shifts for the $v(C=0)$ and $v(C-O)$ frequencies, indicating that $\mathrm{Cu}(\mathrm{II})$ was not coordinating to the oxygens of the ester moiety. There was however evidence of metal coordination to the pyridine and tetrazole nitrogens, with the heterocyclic bands shifting from 1591, 1474 and $1437 \mathrm{~cm}^{-1}$ in the free ligand, to 1615 , 1482 and $1456 \mathrm{~cm}^{-1}$ in the complex, respectively. Elemental analysis revealed a metal to ligand ratio of $1: 1$, therefore it was postulated that the complex could be a dimer similar to those synthesised in Chapter 2, as the elemental analysis results were within tolerance of the calculated percentages for a dimer with four chlorine atoms. The magnetic moment of the complex was 1.7 B.M. which was slightly low for a $\mathrm{Cu}(\mathrm{II})$ complex, but further suggested that the complex could be a dimer with slight interactions between the $\mathrm{Cu}(\mathrm{II})$ atoms. Single green crystals of 3.8 were obtained and analysed by X-ray crystallography, the results of which can be seen in Figure 3.13.

Figure 3.13: Two views of the molecular structure of $\mathbf{3 . 8}$ highlighting the square pyramidal Cu geometry and $[\mathrm{Cu}(\mathrm{II})(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}$ unit with displacement ellipsoids at the $30 \%$ probability level.

The crystal structure of $\mathbf{3 . 8}$ established the $1: 1$ nature of the molecule. The molecular structure consists of a dichloro-bridged dimeric $[\mathrm{Cu}(\mathrm{II})(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}$ unit, with the coordination sphere about each $\mathrm{Cu}(\mathrm{II})$ atom comprising one pyridine N atom, one tetrazole N atom and three chlorine atoms (two of which are $\mu$ - Cl bridging chlorines). The dimeric complex lies on a crystallographic inversion centre which lies at the centre of the $[\mathrm{Cu}(\mathrm{II})(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}$ core and this structure is similar to the previously discussed copper dimer complexes in Chapter 2 (Figure 2.11). ${ }^{121}$ The coordination geometry of each Cu (II) centre is distorted square pyramidal, with the Addison parameter, $t=0.22$ (where $t=0$ for ideal square pyramidal and $t=1$ for ideal trigonal bipyramidal). Each pyridyl tetrazole ligand binds to the $\mathrm{Cu}(\mathrm{II})$ atom through one tetrazole N atom at the $\mathrm{N}-1$ site of the tetrazole ring and through the pyridyl N atom, generating a five-membered chelate ring. The 5-membered tetrazole ring is slightly twisted with respect to the 6 -membered pyridyl ring at an angle of $9.9(2)^{\circ}$ with the 6 atom co-planar ester group almost orthogonal with the tetrazole-pyridine ligand at $83.79(7)^{\circ}$. In the central core, the four-membered $\mathrm{Cu}_{2} \mathrm{Cl}_{2}$ ring is planar and is comparable with those of related dichloro-bridged dimers in the literature. ${ }^{167}$

Reaction of 3.2 with $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}$ yielded a blue crystalline solid, 3.9. The IR spectrum of the complex again indicated that there was no interaction between the $\mathrm{Cu}(\mathrm{II})$ atom and the ester oxygen atoms as no significant shifts were seen for the $v(\mathrm{C}=0)$ and $v(\mathrm{C}-0)$ frequencies. As observed previously, there were shifts seen in the heterocyclic bands of the pyridine and tetrazole rings, indicating that the $\mathrm{Cu}(\mathrm{II})$ atom was interacting with the pyridine and tetrazole nitrogens. Magnetic moment measurements at room temperature recorded a $\mu_{\text {eff }}$ of 2.1 B.M. Elemental analysis yielded a metal to ligand ratio of $1: 2$, therefore it was proposed that complex 3.9 had only one copper atom coordinating to two ligands through the pyridine and tetrazole nitrogens. In order to counter balance the +2 charge on the $\mathrm{Cu}(\mathrm{II})$ it was suggested that two chlorine atoms were also coordinating to the metal centre. The calculated elemental composition of the proposed structure correlated well with the elemental analysis results. The structure was further established when blue crystals of the complex, obtained in MeOH , were analysed by X-ray crystallography. The complex lies on a crystallographic inversion centre (Figure 3.14) with the $\mathrm{Cu}(\mathrm{II})$ centre adopting a slightly distorted octahedral coordination geometry. The $\mathrm{Cu}(\mathrm{II})$ ion is coordinated by two equatorial pyridyl tetrazole ligands and two axial chloride anions. A pseudo Jahn-Teller distortion is observed as elongation along the $\mathrm{N} 22 \cdots \mathrm{Cu} 1 \cdots \mathrm{~N} 22$ coordination bonds is observed. In 3.9 , there is a slight twist within the
ligand so that the planes of the tetrazole and pyridine rings form a dihedral angle of $5.38(13)^{\circ}$; the five atom co-planar ester group is $77.93(5)^{\circ}$ to the 11 -atom ligand ring atoms (the terminal $\mathrm{CH}_{3}$ is not included). The coordination at the Cu centre is asymmetric with the Cu-N bond lengths differing by $0.44 \AA$. Differences can be ascribed to the 5 vs 6 coordination and the more symmetrical nature of 3.8 as compared to 3.9 at the Cu centre. There are no classical hydrogen bonds in 3.9.

Figure 3.14: The molecular structure of $\mathbf{3 . 9}$ with displacement ellipsoids at the $30 \%$ probability level.

Taking into consideration that the ester group was not involved in metal coordination, complexes 3.8 and 3.9 were further reacted with either two equivalents of sodium perchlorate or two equivalents of copper salts in an attempt to achieve coordination with the ester. Unfortunately, these reactions yielded crystalline products which on analysis proved to be starting materials 3.8 and 3.9. At this point, it was decided that conversion of the ester to a carboxylic acid group would have to be undertaken.

### 3.3.2.2 Metal Complexation of in situ Generated Pyridyl Tetrazole Carboxylate Derivatives

Recent work by Yuan and co-workers ${ }^{154}$ using the ligand tetrazole-5-ethyl acetate with $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}$ in NaOH solution resulted in the formation of the polymeric coordination complex seen in Figure 3.7. Two important features of this complex were both the loss of the ester group and the incorporation of the sodium ion into the polymer on complexation. This raised the question as to whether the ligands 3.1 and 3.2 would behave in a similar manner, under similar conditions.

The conversion of an ester to a carboxylic acid is easily achieved using NaOH in MeOH or water. ${ }^{168}$ These reaction conditions were suitable for our purposes as they would have a two-fold benefit; firstly, they would give a carboxylate group on the tetrazole unit and this carboxylate could then become involved in inter- and intramolecular interactions, and secondly, as there would be sodium ions in solution, these ions could interact with the carboxylate groups to form heterometallic CPs. In addition, there was also the practical advantage of not having to isolate and purify the carboxylic acid derivatives. The conditions used and the notations used for the in situ generated ligands herein are shown in Scheme 3.2.

Scheme 3.2: Reagents and conditions: (i) $\mathrm{NaOH}, \mathrm{MeOH}$ or (ii) $\mathrm{NaOH}, \mathrm{MeOH}: \mathrm{H}_{2} \mathrm{O}$.

### 3.3.2.2.1 Reactions with $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}$

The initial reaction involving $\mathbf{3 . 1}$ was carried out in MeOH as the ligand was soluble in this solvent. NaOH was added and the solution was heated to reflux for 1 hour. After this time, it was evident that there was no ester remaining in the solution as there was only a baseline spot present on the TLC plate. $\mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ in MeOH was added to the pH 8 solution and immediately a blue precipitate formed (3.10). IR spectral analysis on the blue solid showed characteristic stretches for the carboxylate group, pyridine and tetrazole rings. In the case of carboxylate derivatives, it is generally accepted that it is possible to distinguish between ionic, monodentate, chelating bidentate or bridging bidentate groups on the basis of calculating the difference in frequency between the anti-symmetric $\mathrm{COO}^{-}$
( $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$) vibration and the symmetric $\mathrm{COO}^{-}\left(\mathrm{v}_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$vibration. ${ }^{169,170}$ The following trend should be seen for $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$:

$$
\Delta_{\text {monodentate }}>\Delta_{\text {ionic }}>\Delta_{\text {bridging bidentate }}>\Delta_{\text {chelating bidentate }}
$$

Monodentate coordination removes the equivalence of the two oxygen atoms and if the bond orders are significantly affected, a pseudo-ester configuration is obtained. This increases the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$, decreases $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$and therefore increases the separation $(\Delta)$ between the two frequencies. ${ }^{169}$ In the IR spectrum of 3.10, the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$and $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$bands were strong bands observed at $1655 \mathrm{~cm}^{-1}$ and $1393 \mathrm{~cm}^{-1}$, respectively. The $\Delta$ value was therefore $262 \mathrm{~cm}^{-1}$. Carboxylates which have $\Delta>200 \mathrm{~cm}^{-1}$ typically coordinate in a monodentate fashion. ${ }^{169}$ Coordination to the tetrazole and pyridine rings was also evident with the heterocyclic bands shifting to 1614,1471 and $1456 \mathrm{~cm}^{-1}$, from 1591, 1474, and $1437 \mathrm{~cm}^{-1}$ respectively in the uncoordinated ligand. Elemental analysis of the blue solid suggested that no sodium was present in the complex but that a 1:1 metal to ligand ratio was possible. The powder was taken up in water and allowed to stand for several days, after which time, blue block crystals formed. IR spectral analysis of the crystals confirmed that they were the same as the original amorphous solid, therefore Xray analysis was performed on a single crystal of the sample.

The X-ray crystal structure of $\mathbf{3 . 1 0}$ is shown in Figure 3.15. The crystal structure of $\mathbf{3 . 1 0}$ reveals that the repeating asymmetric unit contains one Cu atom and one ligand, which was the suggested ratio observed in the elemental analysis. Each $\mathrm{Cu}(\mathrm{II})$ centre is in a distorted octahedral geometry with elongation observed along the $\mathrm{N} 22 \cdots \mathrm{Cu} 1 \cdots \mathrm{~N} 22$ axis. The $\mathrm{Cu}(\mathrm{II})$ ion is coordinated by four nitrogen atoms of two $\mathbf{3 . 1}$ (pytza) ligands in the equatorial plane and two axial oxygen atoms from two other 3.1(pytza) ligands lying above and below the $\mathrm{Cu}(\mathrm{II})$ ion (Figure 3.15). The molecule is neutral overall since the charges on the copper ion are balanced by the two singly charged anionic carboxylate ligands. Thus, each ligand (that exhibits a considerable twist of $15.0(3)^{\circ}$ between the pyridine/tetrazole rings) is involved in bonding one copper ion through the pyridine N atom and the tetrazole $\mathrm{N}-1$ atom, in a bidentate manner, while also bonding to a second copper ion through the 02 oxygen atom of the carboxylate group in a monodentate fashion. This method of bridging is common in carboxylate complexes. ${ }^{171}$

Figure 3.15: The molecular structure of $\mathbf{3 . 1 0}$ with displacement ellipsoids at the 30\% probability level and highlighting the $\mathrm{Cu}-\mathrm{O}_{\text {carboxylate }}$ binding.

Only one of the two carboxylate oxygen atoms are involved in bonding within the polymeric chain. The partial packing diagram in Figure 3.16 shows that the complex is oriented in a stepwise manner with interactions between the copper ions and the carboxylate groups only occurring along the stepwise direction. No strong interactions are observed between the 1-D steps.

Figure 3.16: The 1-D chain formation in $\mathbf{3 . 1 0}$ (with displacement ellipsoids at the $30 \%$ probability level) highlighting the polymeric nature of the $\mathrm{Cu}-\mathrm{O}_{\text {carboxylate }}$ binding. Hydrogen atoms omitted for clarity.

The formation of this 1-D CP was a promising indication that the in situ generated carboxylate derivatives could be a useful organic linker in the construction of frameworks. However, improvements on the reaction conditions were sought. This was in order to obtain more crystalline products from the reaction mixture, achieve higher dimensionality in the frameworks and to perhaps incorporate sodium ions into the framework. Hence, the next reaction with 3.1 was carried out in $\mathrm{H}_{2} \mathrm{O}$ and MeOH in a 10:1 ratio, as it was thought that the solubility of the complex would have been better and therefore crystalline material could form slowly in the reaction medium. This reaction successfully produced blue-green block crystals on allowing the solution to stand for one day. Interestingly, the

IR spectrum and the elemental analysis of this compound, 3.11, suggested that it was an entirely different compound to the one synthesised in MeOH . The IR spectrum of compound 3.11 again suggested that monodentate coordination was occurring between a carboxylate oxygen and the $\mathrm{Cu}(\mathrm{II})$ ion, with the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$and $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$bands observed at $1650 \mathrm{~cm}^{-1}$ and $1359 \mathrm{~cm}^{-1}$. However, another mode of binding was also evident. Intense bands were present at $1610 \mathrm{~cm}^{-1}$ and $1458 \mathrm{~cm}^{-1}$, and these were postulated to be additional $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$and $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$vibrations, respectively. Therefore, a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$value of $152 \mathrm{~cm}^{-1}$ would exist. It is generally accepted that $\Delta$ values $<200 \mathrm{~cm}^{-1}$ belong to chelating and/or bridging carboxylate ligands. ${ }^{169}$ Elemental analysis indicated that the composition of the complex was 1:2 metal to ligand, hence it could have been possible for one ligand to be binding in a monodentate manner, and another to be binding in a chelating or bridging manner.

Single crystals of $\mathbf{3 . 1 1}$ were analysed by X-ray crystallography and this revealed that there was indeed two modes of carboxylate coordination present. The molecular structure, shown in Figure 3.17, consists of one ligand behaving in a bridging fashion, via one carboxylate oxygen binding in a monodentate manner and two nitrogens binding in a chelating fashion. The second ligand is only involved in chelation through its carboxylate group, with the remaining nitrogen donors at most only engaging in hydrogen bonding. This behaviour is reminiscent of the behaviour of bisphosphines whereby they can bind to metals in typically a bridging or chelating manner or via binding through one of the phosphorus atoms. ${ }^{172}$ This bonding results in a dimeric molecular complex, with the asymmetric unit comprising one $\mathrm{Cu}(\mathrm{II})$ metal centre, one $\mathrm{H}_{2} \mathrm{O}$ molecule and two 3.1(pytza) ligands. The complex is built up about inversion centres midway between the two $\mathrm{Cu}(\mathrm{II})$ metal centres.

Figure 3.17: The molecular structure of $\mathbf{3 . 1 1}$ with displacement ellipsoids at the $30 \%$ probability level.

Each $\mathrm{Cu}(\mathrm{II})$ ion is in a distorted octahedral geometry, although the very long Cu1 $\cdots 03$ distance ( $2.76 \AA$ ) implies that a five-coordinate description may be equally valid. The coordination sphere around each $\mathrm{Cu}(\mathrm{II})$ centre consists of (i) a pyridine nitrogen atom and a tetrazole N atom from one ligand, (ii) one oxygen atom from the carboxylate group of a second ligand, (iii) two oxygen atoms from the carboxylate group of a third ligand, and (iv) a $\mathrm{H}_{2} \mathrm{O}$ molecule that completes the hexa-coordinate geometry. The ligands in $\mathbf{3 . 1 1}$ are not planar, and as has been noted previously, they exhibit a measure of interplanar distortion and exhibit dihedral angles of $7.4(2)^{\circ}$ and $6.8(3)^{\circ}$ between the planes of the pyridine and tetrazole rings. The 16 membered ring that is formed by the two bridging ligands possesses a square-like cavity with dimensions of $4.13 \AA$ by $5.01 \AA$.

The coordination of the $\mathrm{H}_{2} \mathrm{O}$ molecule to the $\mathrm{Cu}(\mathrm{II})$ metal centre is the most obvious difference between the structures of $\mathbf{3 . 1 0}$ and $\mathbf{3 . 1 1}$ and its presence has an effect on the resulting coordination network (Figures 3.18 and 3.19). The water molecule participates in strong hydrogen bonding involving reciprocal water $01 \mathrm{~W} \cdots \mathrm{O}_{\text {carboxylate }}$ hydrogen bonds about inversion centres in an inorganic complex that is rich in hydrogen bond acceptors; the intermolecular $0 \cdots 0$ distances are $2.680(5)$ and $2.736(5) \AA$. The strong hydrogen bonding between dimers thus generates a hydrogen bonded chain along the $b$-axis direction. Hydrogen bonded chains are further linked into a 2-D network of hydrogen bonds by a combination of several C-H $\cdots \mathrm{O} / \mathrm{N}$ interactions (Figures 3.18 and 3.19).

Figure 3.18: The primary hydrogen bonding (shown in blue) involving 01W and linking molecules of 3.11.

Figure 3.19: A view of hydrogen bonding between molecules of 3.11 in the three hydrogen bonded chains propagating along the $b$-axis direction.

Therefore, it was evident that reaction solvent had a big influence on the resulting structures of the complexes. This prompted similar investigations into the behaviour of the N -2 regioisomer (3.2) in different solvents. Thus, in situ hydrolysis of $\mathbf{3 . 2}$ was carried out in either MeOH or $\mathrm{MeOH}: \mathrm{H}_{2} \mathrm{O}$ mixtures, and after 1 hour $\mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ was added to the reactions. In the reaction carried out in MeOH , a pale green precipitate, 3.12, formed immediately on addition of the metal salt. This precipitate was analysed by IR spectroscopy and again it was evident from the abundance of peaks in the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$and $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$region that the ligands were coordinating to the metal centre via more than one coordination mode. There was also a broad signal at $\sim 3262 \mathrm{~cm}^{-1}$ which suggested that hydroxide anions could be involved in bonding. Elemental analysis suggested a 1:1 metal to ligand ratio. Due to the success of growing crystals of $\mathbf{3 . 1 0}$ from an aqueous solution, attempts at growing crystals of $\mathbf{3 . 1 2}$ were attempted under similar conditions. However, solubility of the complex was very poor in most solvents, and heat was required to dissolve the material into $\mathrm{H}_{2} \mathrm{O}$ and DMSO. This often resulted in changes to the molecular structure of 3.12, and this was evident on performing IR analysis of the materials which formed in the $\mathrm{H}_{2} \mathrm{O}$ and DMSO solutions over time. In some cases, conversion to $\mathbf{3 . 1 3}$ was observed (Figure 3.21). Therefore, a proposed structure of $\mathbf{3 . 1 2}$ was tentatively suggested and can be seen in Figure 3.20.

Figure 3.20: Proposed structure of $\mathbf{3 . 1 2}$.

To investigate the effect of using $\mathrm{H}_{2} \mathrm{O}$ as the reaction medium, 3.2 was again hydrolysed in situ in a mixture of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{MeOH}(10: 1)$. On addition of $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}$, a blue crystalline solid formed almost immediately. The IR spectrum of the solid displayed a very broad stretch (2973-3433 $\mathrm{cm}^{-1}$ ) centred at $3166 \mathrm{~cm}^{-1}$, indicating that there could be coordinated $\mathrm{H}_{2} \mathrm{O}$ molecules and extensive hydrogen bonding present in the complex. An absence of a peak around $1713 \mathrm{~cm}^{-1}$ indicated that the carboxyl group of 3.13 was deprotonated. The $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$band was visible at $1628 \mathrm{~cm}^{-1}$ and the $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$band appeared at $1374 \mathrm{~cm}^{-1}$. This yielded a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\mathrm{sym}}\left(\mathrm{COO}^{-}\right)\right)$value of $254 \mathrm{~cm}^{-1}$, which corresponded to monodentate carboxylate coordination, however it was noted that the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$band was lower in frequency compared to $\mathbf{3 . 1 0}$ and $\mathbf{3 . 1 1}$. Metal coordination to the pyridyl tetrazole moiety was also alluded to, as shifts in the heterocyclic bands $(v(C=N), v(N=N))$ to 1452,1465 and $1614 \mathrm{~cm}^{-1}$ were visible. Elemental analysis indicated a 1:2 metal to ligand composition.

To achieve single crystals of $\mathbf{3 . 1 3}$ that were suitable for X-ray crystallography, a number of parameters were altered. It was found that by reducing the ratio of MeOH in the reaction medium, the solid became less powdered in appearance and that crystal sizes became bigger. It also became apparent that slow cooling also resulted in larger single crystals. Therefore, the optimum conditions to obtain large single crystals of $\mathbf{3 . 1 3}$ were to employ $100 \%$ water as the reaction medium followed by slow cooling after addition of the metal salt. The obtained crystals were solved by X-ray crystallography and the molecular structure and primary hydrogen bonding system of $\mathbf{3 . 1 3}$ is depicted in Figure 3.21.

Figure 3.21: The molecular structure of $\mathbf{3 . 1 3}$ with displacement ellipsoids at the $30 \%$ probability level including the primary intermolecular 0-H $\cdots 0$ hydrogen bonds.

Each $\mathrm{Cu}(\mathrm{II})$ ion is in a distorted octahedral geometry, resulting from the coordination of two 3.2 (pytza) ligands through the pyridine N atom and one tetrazole N atom from each ligand and two $\mathrm{H}_{2} \mathrm{O}$ molecules, yielding an isolated complex. Jahn-Teller elongation is observed along the $\mathrm{N} 2 \cdots \mathrm{Cu} 1 \cdots \mathrm{~N} 2$ axis ( $2.34 \AA$ compared to $2.02 \AA$ for all other $\mathrm{Cu}-\mathrm{L}$ bonds). This observation of an elongated coordination bond between the metal ion and the tetrazole nitrogens correlates well with previously discussed distorted octahedral complexes in this Chapter. Each $\mathbf{3 . 2}$ (pytza) ligand is negatively charged through the loss of a carboxylate proton, thereby making the overall molecule neutral. Also, both carboxylate C-O bond lengths are similar in bond length, therefore are intermediate between single and double bonds. This would justify a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right.$) value of $254 \mathrm{~cm}^{-1}$, which is typical of ionic carboxylate values and are generally lower than monodentate binding carboxylates. Each $\mathrm{H}_{2} \mathrm{O}$ molecule is involved in two hydrogen bond interactions with the carboxylate groups of two different $\mathbf{3 . 2}$ (pytza) ligands, as shown in Figures 3.22, forming a 3-D network. This strong $0-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonding creates a large network of interactions throughout the 3-D hydrogen bonded structure with molecular niches, however these niches are too small to contain a solvent molecule.

Figure 3.22: Part of the intricate intermolecular $0-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonding in structure of 3.13 with displacement ellipsoids at the $30 \%$ probability level.

During the course of this work, Yang and co-workers published their work on CPs utilising 5-(2-pyridyl)tetrazole-2-acetic acid (Figure 3.23). ${ }^{173}$ Under solvothermal conditions, and after longer reaction times ( 48 h ), they obtained several hydrogen bonded networks similar to 3.13. Herein, we present the first $\mathrm{Cu}(\mathrm{II})$ coordination network of this type and present a new less stringent synthetic route to obtain such networks.

Figure 3.23: 5-(2-pyridyl)tetrazole-2-acetic acid was used in the solvothermal synthesis of coordination architectures. ${ }^{173}$

### 3.3.2.2.2 Reactions with $\mathrm{ZnCl}_{2}$

Reactions of 3.1 and 3.2 with $\mathrm{ZnCl}_{2}$ were carried out in the same manner as in section 3.3.2.2.1. The reaction of $\mathbf{3 . 1}$ with NaOH in MeOH followed by the addition of a methanolic solution of $\mathrm{ZnCl}_{2}$ yielded a clear solution which was allowed to stand for several days. A crystalline creamy white solid formed which was filtered and washed with MeOH. The IR spectrum of the solid, $\mathbf{3 . 1 4}$, was a simple spectrum. The absence of the characteristic band for the protonated carboxylate group ( $1724 \mathrm{~cm}^{-1}$ ) indicated complete deprotonation of 3.1 (pytza). A $v_{\text {asym }}\left(\mathrm{COO}^{-}\right.$) band could clearly be seen at $1650 \mathrm{~cm}^{-1}$, and the corresponding $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$band was observed at $1365 \mathrm{~cm}^{-1}$. This gave a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$ value of $285 \mathrm{~cm}^{-1}$, suggesting a monodentate coordination of the carboxylate group to the Zn (II) atom. Shifts for the heterocyclic $v(\mathrm{C}=\mathrm{N})$ and $v(\mathrm{~N}=\mathrm{N})$ vibrations were also noted to have shifted from 1478, 1438 and $1354 \mathrm{~cm}^{-1}$ to 1610,1474 and $1462 \mathrm{~cm}^{-1}$ respectively. This indicated that $\mathrm{Zn}(\mathrm{II})$ coordination to the pyridine and tetrazole nitrogens was also occurring. There was no indication of the presence of coordinating solvent molecules or hydrogen bonding in the complex in the IR spectrum, as peaks in the region of $3000 \mathrm{~cm}^{-1}$ were only due to aliphatic stretches. Elemental analysis suggested that the composition of the complex was $1: 1$ metal to ligand ratio. Therefore it was proposed that the $\mathrm{Zn}(\mathrm{II})$ atom was in an octahedral geometry, with four coordination sites taken up by chelation to two 3.1(pytza) ligands via four nitrogens and the remaining two coordination sites occupied by two carboxylate oxygens from another two 3.1(pytza) ligands bonding in a monodentate manner. This would lead to a 1-D polymeric chain like that seen in 3.10. The proposed structure of the complex is presented in Figure 3.24. The ${ }^{1} \mathrm{H}$ NMR spectral
analysis of 3.14 was carried out in $d_{6}$-DMSO and resulted in a simple spectrum. The spectrum showed differences in shifts from those in the free protonated $\mathbf{3 . 1}$ (pytza) ${ }^{1} \mathrm{H}$ NMR spectrum, indicating that the complex was not decomposing into free ligand in the $d_{6}$-DMSO solution.

Figure 3.24: Proposed structure of 3.14.

Five signals in total were observed, which would be expected if the complex had the structure as depicted in Figure 3.22. Four multiplets arising from the pyridyl protons were seen at $7.57,8.04,8.25$ and 8.68 ppm and a singlet was observed 5.53 ppm which integrated for twice that of the pyridyl protons, hence this signal was assigned to the $\mathrm{CH}_{2}{ }^{-}$ tet protons.

When 3.1 was reacted with NaOH in $\mathrm{H}_{2} \mathrm{O}: \mathrm{MeOH}(10: 1)$ followed by the addition of an aqueous solution of $\mathrm{ZnCl}_{2}$, the resulting clear solution was allowed to stand for several days. The resulting crystalline solids were filtered off and washed with $\mathrm{H}_{2} \mathrm{O}$. On analysis of the IR spectrum of the white solid (3.15), it was suggested that the carboxylate was either ionic or adopting a monodentate coordination to the metal centre, as the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$ vibration was observed at $1650 \mathrm{~cm}^{-1}$ and the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$was observed at $1364 \mathrm{~cm}^{-1}$, yielding a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$value of $286 \mathrm{~cm}^{-1}$. There was also a broad stretch centred at $\sim 3126 \mathrm{~cm}^{-1}$ indicating the presence of $\mathrm{H}_{2} \mathrm{O}$ molecules in the complex. Elemental analysis suggested that the complex possessed a 1:2 metal to ligand ratio. The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{3 . 1 5}$ displayed five signals: four signals were present in the aromatic region and a singlet was present at 5.48 ppm . Considering the elemental analysis results and the observed NMR signals, it was suggested that the two ligands were in the same environment, thus forming a symmetrical molecule. The proposed structure can be seen in Figure 3.25.

Figure 3.25: Proposed structure of 3.15.

The reaction of 3.2 with NaOH and $\mathrm{ZnCl}_{2}$ in MeOH resulted in a clear solution which was allowed to stand for several days and the resulting solids were filtered to yield $\mathbf{3 . 1 6}$ as a cream solid which was firstly was analysed by IR spectroscopy. In the IR spectrum, an absence of a peak at $1713 \mathrm{~cm}^{-1}$ indicated that the carboxylate was in its deprotonated form. The $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$stretch was observed at $1645 \mathrm{~cm}^{-1}$ and the $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$stretch was observed at $1383 \mathrm{~cm}^{-1}$, yielding a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$value of $263 \mathrm{~cm}^{-1}$. This suggested that the carboxylate was binding in a monodentate or ionic manner. $\mathrm{Zn}(\mathrm{II})$ coordination to the pyridine and tetrazole nitrogens was also evident with shifts of the $v(\mathrm{C}=\mathrm{N})$ and $v(\mathrm{~N}=\mathrm{N})$ bands moving from 1604, 1434 and 1429 in the free ligand to 1611, 1451 and $1417 \mathrm{~cm}^{-1}$ in the complex. New bands at higher frequencies (3523, 3423 and $3090 \mathrm{~cm}^{-1}$ ) appeared in the IR spectrum of the complex. These bands were attributed tentatively to the stretching vibrations of OH groups from coordinated solvent. Elemental analysis of the compound indicated that the composition of the complex was 1:1 metal to ligand. In the ${ }^{1} \mathrm{H}$ NMR spectrum of the product, there were four multiplets, each with a relative integration of one, corresponding to four aromatic pyridine protons, and a singlet at 5.44 ppm with a relative integration of two, which corresponded to the $\mathrm{CH}_{2}$-tet protons which would be expected to remain after hydrolysis. On inspection of the ${ }^{13} \mathrm{C}$ NMR spectrum of the product, signals were as expected for the carboxylate, pyridine and tetrazole carbons. Of interest however, were the presence of two signals at 48.5 and 55.3 ppm. One would expect for there to be only one carbon signal for the $\mathrm{CH}_{2}$-tet carbon in this region. After carrying out a DEPT-135 experiment, it was evident that the signal at 55.3 ppm corresponded to a $\mathrm{CH}_{2}$ carbon, and that the signal at 48.5 ppm corresponded to either a CH or a $\mathrm{CH}_{3}$ carbon. Taking into account that the reaction solvent was MeOH , it was postulated that this signal could arise from a coordinated $\mathrm{OCH}_{3}$ group. The lack of visible signals for these protons in the ${ }^{1} \mathrm{H}$ NMR spectrum could have been due to overlapping with the substantial $d_{6}$-DMSO residual solvent peak. Taking all this information into consideration, a structure was proposed, a representation of which can be seen in Figure
3.26. It was proposed that a dinuclear complex existed, with both Zn (II) atoms in a tetrahedral geometry, as $\mathrm{Zn}(\mathrm{II})$ generally prefers this coordination geometry over square planar. ${ }^{132}$ One $\mathrm{Zn}(\mathrm{II})$ metal centre is coordinated by two 3.2 (pytza) ligands via four nitrogens, with the $2^{+}$charge being counter balanced by two negatively charged 3.2 (pytza) ligands. The second $\mathrm{Zn}(\mathrm{II})$ metal centre is proposed to be coordinated by two carboxylate oxygens from two 3.2 (pytza) ligands, both bonding in a monodentate manner, and two methoxy groups, whose negative charge would counter balance the $2^{+}$ charge on this $\mathrm{Zn}(\mathrm{II})$ metal centre.

Figure 3.26: The proposed structure of a subunit of the coordination polymer 3.16.

Reaction of 3.2 with NaOH was then carried out in $\mathrm{H}_{2} \mathrm{O}$, followed by the addition of an aqueous solution of $\mathrm{ZnCl}_{2}$. The resulting crystalline solid, 3.17, was filtered off and washed with water. The IR spectrum of $\mathbf{3 . 1 7}$ again lacked a peak at $1713 \mathrm{~cm}^{-1}$, indicating that the carboxylate was in the deprotonated form. The spectrum did display a $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$stretch at $1638 \mathrm{~cm}^{-1}$ and a $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$stretch at $1373 \mathrm{~cm}^{-1}$, giving a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$ value of $265 \mathrm{~cm}^{-1}$. Again, it was noted that the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$and $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$stretches were of lower frequencies compared to previous monodentate species, therefore the presence of ionic carboxylates was also taken into consideration. Broad signals (2867-3419 cm ${ }^{-1}$ ) centred at $3236 \mathrm{~cm}^{-1}$ were also visible in the IR spectrum, which suggested that there were coordinating solvent molecules and hydrogen bonding present in the complex. Elemental analysis of the complex indicated a 1:2 metal to ligand composition. As previously mentioned, work by Yang et al. involved the use of 5-(2-pyridyl)tetrazole-2acetic acid (Figure 3.23) in constructing coordination networks. In the course of this work, they obtained a Zn (II) complex solvothermally after 48 h using a 7:1 ratio of MeOH and $\mathrm{H}_{2} \mathrm{O} .{ }^{174}$ The data they obtained for this complex correlated with the data obtained for 3.17. The group also obtained a crystal structure of the complex, and this can be seen in Figure 3.27.

Figure 3.27: Crystal structure of a $\mathrm{Zn}(\mathrm{II})$ complex obtained from a solvothermal reaction in $\mathrm{H}_{2} \mathrm{O}$ and MeOH after 48 h. ${ }^{174}$

The data obtained for compound $\mathbf{3 . 1 7}$ is in agreement with the crystal structure obtained by Yang and co-workers, and is analogous to the $\mathrm{Cu}(\mathrm{II})$ complex 3.13 synthesised previously.

### 3.3.2.2.3 Reactions with $\mathrm{NiCl}_{2} .6 \mathrm{H}_{2} \mathrm{O}$

The addition of $\mathrm{NiCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ to a solution of $\mathbf{3 . 1}$ and NaOH in MeOH led to a pale blue precipitate forming in solution, which was filtered and dried to yield 3.18. The blue powder was analysed by IR spectroscopy which revealed that no protonated carboxylate was present as there was an absence of the characteristic peak for such a group. A $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$stretch was observed at $1646 \mathrm{~cm}^{-1}$ and a $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$stretch was observed at $1367 \mathrm{~cm}^{-1}$, giving a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$value of $279 \mathrm{~cm}^{-1}$. This suggested that the carboxylate groups were coordinating to the metal in a monodentate manner. Coordination of $\mathrm{Ni}(\mathrm{II})$ to the pyridine and tetrazole nitrogens was also evident as significant heterocyclic stretches were observed to shift to 1615,1479 and $1463 \mathrm{~cm}^{-1}$ from 1590,1473 and $1438 \mathrm{~cm}^{-1}$, which were the heterocyclic frequencies observed in the IR spectrum of the free ligand. There was also a substantial broad stretch visible at 3401 $\mathrm{cm}^{-1}$, indicating that OH groups from solvent or the metal hydrate were possibly present. Elemental analysis indicated that the composition of the complex was $1: 1$ metal to ligand. Hence, it was proposed that the $\mathrm{Ni}(\mathrm{II})$ atom possessed an octahedral geometry, with the coordination sphere being occupied by four 3.1(pytza) ligands; two ligands coordinating via their pyridyl and tetrazole nitrogens and the remaining two coordinating in a monodentate manner via their carboxylate oxygens. The presence of solvent which was indicated in the IR spectrum of $\mathbf{3 . 1 8}$ is proposed to be a molecule of water that could be present in the sample. The proposed structure would have the same arrangement as seen
for 3.10, forming a 1-D coordination polymer. When reacting 3.1(pytza) with $\mathrm{NiCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ in aqueous media ( $\mathrm{H}_{2} \mathrm{O}: \mathrm{MeOH}, 10: 1$ ) a blue precipitate formed over time. The data obtained for this solid (3.19) correlated with that of 3.18, hence it was proposed that in this case, solvent had no effect on the final structures and $\mathbf{3 . 1 9}$ was the same product as 3.18.

A pale blue crystalline solid, $\mathbf{3 . 2 0}$, formed on addition of methanolic $\mathrm{NiCl}_{2} .6 \mathrm{H}_{2} \mathrm{O}$ to 3.2 (pytza) in NaOH and MeOH . The IR spectrum of $\mathbf{3 . 2 0}$ displayed a $\nu_{\text {asym }}\left(\mathrm{COO}^{-}\right)$peak at $1630 \mathrm{~cm}^{-1}$ and a $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$peak at $1373 \mathrm{~cm}^{-1}$. This gave a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$ value of $257 \mathrm{~cm}^{-1}$ which suggested either a monodentate or an ionic carboxylate was present in the complex. A broad stretch centred at $3234 \mathrm{~cm}^{-1}$ was also observed, indicating that some solvent molecules were present and perhaps involved in hydrogen bonding. In the analogous reaction that was carried out in a mixture of $\mathrm{H}_{2} \mathrm{O}$ and MeOH , a pale blue solid, 3.21, precipitated. On IR spectral analysis of this solid, the same stretches were observed, suggesting that in this case the choice of solvent did not affect the final structures. The elemental analysis of both compounds pointed towards a $1: 2$ metal to ligand composition. Hence, the structure of $\mathbf{3 . 2 0}$ and $\mathbf{3 . 2 1}$ was proposed to comprise of an octahedral Ni(II) centre, with two $\mathbf{3 . 2}$ (pytza) ligands binding to the metal centre via their pyridine and tetrazole nitrogens and the remaining two coordination sites occupied by two $\mathrm{H}_{2} \mathrm{O}$ molecules (Figure 3.28). It was postulated that the degree of hydration of the $\mathrm{NiCl}_{2}$ salt played an important role in the synthesis of this coordination network, as it seemed to provide enough $\mathrm{H}_{2} \mathrm{O}$ molecules in both solvents to produce this structure.

Figure 3.28: Proposed structure of $\mathbf{3 . 2 0}$ and $\mathbf{3 . 2 1}$.

### 3.3.2.2.4 Reactions with $\operatorname{Co}(S C N)_{2}$

The reactions of $\mathbf{3 . 1}$ and $\mathbf{3 . 2}$ with $\mathrm{Co}(\mathrm{SCN})_{2}$ were carried out under the same conditions as in previous sections. In the reaction of $\mathbf{3 . 1}$ with NaOH in MeOH followed by the addition of $\operatorname{Co}(\mathrm{SCN})_{2}$, a beige powder, 3.22, precipitated immediately on addition of the metal salt. The solid was analysed by IR spectroscopy and the IR spectrum revealed that no protonated carboxylate was present as no peak was present at $1724 \mathrm{~cm}^{-1}$. The $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$ and $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$bands were observed at 1649 and $1361 \mathrm{~cm}^{-1}$ respectively. This gave a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$value of $288 \mathrm{~cm}^{-1}$, indicating that the carboxylate was coordinating to the metal centre in a monodentate manner. It was also evident that metal coordination to the pyridine and tetrazole nitrogens was occurring, as shifts in the $v(\mathrm{C}=\mathrm{N})$ and $v(\mathrm{~N}=\mathrm{N})$ bands to higher frequencies compared to the free ligand were visible. The IR spectrum also revealed that no thiocyanate anions were present in the complex, with an absence of a characteristic $v(\mathrm{C}-\mathrm{N})_{\mathrm{scN}}$ stretch at $\sim 2070 \mathrm{~cm}^{-1}$. Elemental analysis of $\mathbf{3 . 2 2}$ indicated a 1:1 metal to ligand composition. Hence, it was postulated that the structure of 3.22 was analogous to that of 3.10; a 1-D polymeric structure with the octahedral Co(II) centre coordinated to two $\mathbf{3 . 1}$ (pytza) ligands via the pyridine and tetrazole nitrogens, and two 3.1(pytza) ligands via the monodentate coordinating carboxylate oxygens.

A pink solution resulted from the reaction of $\mathbf{3 . 1}$ with NaOH in a mixture of $\mathrm{H}_{2} \mathrm{O}$ and MeOH followed by the addition of an aqueous solution of $\operatorname{Co}(\mathrm{SCN})_{2}$. On standing for several days an orange solid formed which was isolated. The IR spectrum of the product $\mathbf{3 . 2 3}$ displayed $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$and $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$stretches at 1650 and $1360 \mathrm{~cm}^{-1}$ respectively and complete deprotonation of the carboxylate was indicated by lack of a vibration at $1724 \mathrm{~cm}^{-1}$. The $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$value was $290 \mathrm{~cm}^{-1}$, therefore monodentate coordination of the carboxylate was possible. However, the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$stretch was broad with a shoulder at $1611 \mathrm{~cm}^{-1}$ which alluded to an additional mode of carboxylate coordination being present, especially if the corresponding $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$frequency was the peak visible at 1462 $\mathrm{cm}^{-1}$. Comprehensive assignments of these peaks however was hampered due to the heterocyclic stretches of the pyridine and tetrazole rings vibrating in the same region. New bands at $\sim 3429 \mathrm{~cm}^{-1}$ indicated solvent molecules were present in the complex and the absence of a $v(\mathrm{C}-\mathrm{N})_{\mathrm{scN}}$ stretch at $\sim 2070 \mathrm{~cm}^{-1}$ indicated that there were no thiocyanate anions present. Elemental analysis suggested that the composition of the complex was 1:2 metal to ligand, therefore it was proposed that the complex consisted of a dinuclear octahedral Co(II) arrangement. Each Co(II) centre was proposed to coordinate to two nitrogens from one 3.1(pytza) ligand, one carboxylate oxygen from another 3.1(pytza) ligand, two oxygens from a third $\mathbf{3 . 1}$ (pytza) ligand and a $\mathrm{H}_{2} \mathrm{O}$ molecule. This would
resemble the arrangement seen in a previously discussed Cu(II) complex, $\mathbf{3 . 1 1}$ (Figure 3.17).

The reaction of 3.2 with NaOH in MeOH followed by the addition of $\mathrm{Co}(\mathrm{SCN})_{2}$ in MeOH yielded a purple solution from which a pink precipitate formed almost immediately. This pink precipitate was filtered and air dried and then subsequently analysed by IR spectroscopy. A number of prominent peaks could be observed in the IR spectrum. An intense band was observed at $1608 \mathrm{~cm}^{-1}$ which was assigned to the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$stretch of the carboxylate group. A strong band was also present at $1397 \mathrm{~cm}^{-1}$ which was assigned to the $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$stretch of the carboxylate group. The presence of OH containing groups was also evident as a broad intense band centred at $3393 \mathrm{~cm}^{-1}$ was observed. The presence of thiocyanate anions was revealed as two strong $v(\mathrm{C}-\mathrm{N})_{\mathrm{scN}}$ stretching frequencies were observed at 2092 and $2116 \mathrm{~cm}^{-1}$. The SCN group may coordinate to a metal through the nitrogen or the sulfur or through both. The $v(\mathrm{C}-\mathrm{N})_{\text {scN }}$ stretching frequencies are generally lower in N -bonded complexes (near or below $2050 \mathrm{~cm}^{-1}$ ) than in S-bonded complexes, which have values near $2100 \mathrm{~cm}^{-1}$. Frequencies well above 2100 $\mathrm{cm}^{-1}$ are generally bridging complexes. ${ }^{150}$ On observing $v(\mathrm{C}-\mathrm{N})_{\text {scs }}$ frequencies appearing near $2100 \mathrm{~cm}^{-1}$, it was proposed that the thiocyanate anions were $S$-bonded. On observation of the colour of the solid and its $\mu_{\text {eff }}$ value of 4.5 B.M., it could be presumed that the geometry of the metal centre was octahedral. ${ }^{132}$ Therefore the Co(II) centre had to be coordinated by six atoms. If the pink sample was dried under vacuum the colour changed from pink to an intense blue. This implied that solvent molecules present in the octahedral complex were removed, thereby forming a tetrahedral complex. On leaving the solid in air at room temperature for $\sim 1 \mathrm{~h}$, the colour reverted back to pink again, implying that atmospheric water was being absorbed by the complex and hence forming an octahedral complex again. It is well known that Co(II) forms mainly octahedral or tetrahedral species, and there are several cases in which two types with the same ligand are both known. For a $\mathrm{d}^{7}$ ion like cobalt, ligand field stabilisation energies do not discriminate against either geometry compared to lower or higher $\mathrm{d}^{\mathrm{n}}$ ions. Therefore the abundance of complexes with both geometries are due to the small stability difference between them. ${ }^{132}$ The change in geometry of the metal centre is concomitant with a change in the crystal field splitting, which is illustrated in Figure 3.29, for octahedral and tetrahedral fields. $\Delta_{\text {tet }}$ is significantly smaller than $\Delta_{\text {oct, }}$ implying that smaller amounts of energy are needed for an $t_{2} \leftarrow e$ transition in the tetrahedral field than a $e_{\mathrm{g}} \leftarrow t_{2 g}$ transition in an octahedral field which often results in octahedral and tetrahedral complexes often having different colours. ${ }^{56}$

Figure 3.29: Crystal field splitting diagram for octahedral (left hand side) and tetrahedral (right hand side) fields.

Elemental analysis, IR and UV-Vis spectroscopy were carried out on the sample in both its pink and blue states. Elemental analysis indicated that on undergoing a geometry change, solvent molecules were removed as the percentage of carbon and nitrogen increased by $\sim 4 \%$. The IR spectra of both complexes also demonstrated that solvent molecules were removed on going from octahedral to tetrahedral as the broad stretch at $3393 \mathrm{~cm}^{-1}$ had decreased in intensity in the blue sample. Hence, two structures were proposed and these can be seen in Figure 3.30.

3.24a

3.24b

Figure 3.30: Proposed structures for 3.24; 3.24a represents the proposed octahedral subunit of a coordination polymer and $\mathbf{3 . 2 4 b}$ represents the proposed tetrahedral subunit of a coordination polymer which is formed on loss of solvent molecules.

Studies of electronic spectra of metal complexes can provide information about their structure and bonding. The colours of transition metal complexes arise from the splitting of the $d$ orbitals caused by the presence of coordinating ligands. When the energy difference between the orbitals matches the energy of incoming light, light is absorbed by
the solution and electronic transitions occur between the electronic energy levels. Transitions can occur between $d$ orbitals on the metal centre ( $d$ - $d$ transitions) or between metal- and ligand-centred orbitals which transfer charge from metal to ligand or ligand to metal. Electronic transitions obey certain selection rules, one of which is the Laporte selection rule (that there must be a change in parity). Hence, the allowed transitions are $s$ $\rightarrow p, p \rightarrow d, d \rightarrow f$ and forbidden transitions are $s \rightarrow s, p \rightarrow p, d \rightarrow d, f \rightarrow f, s \rightarrow d, p \rightarrow f$. The observation of the Laporte forbidden $d$ - $d$ transitions can be explained by a mechanism called 'vibronic coupling'. Octahedral complexes possess a centre of symmetry, but molecular vibrations result in its temporary loss. When symmetry is briefly lost, mixing of $d$ and $p$ orbitals occur and a $d-d$ transition involving an orbital of mixed $p d$ character can occur although the absorption is still relatively weak. In tetrahedral complexes, where there is no centre of symmetry, $p d$ mixing can occur to a greater extent and so the probability of $d$ - $d$ transitions occurring is greater than in octahedral complexes. 56 Absorption bands are described by $\lambda_{\max }$ and $A_{\max }$ and $\varepsilon_{\text {max }} \varepsilon_{\text {max }}$ indicates how intense an absorption is and is related to $\mathrm{A}_{\text {max }}$ by the following Beer-Lambert law:

$$
A_{\max }=\text { عlc } \quad \text { Eqn. } 3.1
$$

where 1 represents the path length of the cell and $c$ is the molar concentration in the cell. Figure 3.31 displays UV spectra recorded from 5 mM solutions of both the pink (3.24a) and blue samples (3.24b) (represented by the pink and blue traces respectively). Clear differences between the spectra were observed. The complimentary colour of the absorbed light yields the colour of the sample, therefore you would expect the pink sample to absorb in the green/yellow region of the spectrum. This indeed is manifested in Figure 3.31 as the pink sample possesses a $\lambda_{\max }$ at 512 nm . In the case of blue coloured solutions, you would expect an absorbance in the orange region (600-640 nm) and this is concurrent with the observed $\lambda_{\max }$ of 620 nm . It is also evident from the spectra that the blue solution has a more intense absorbance than the pink solution, with $\varepsilon_{\max }$ of 13.2 $\mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}$ for the pink sample and $137.6 \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}$ for the blue sample. For centrosymmetric complexes like octahedral complexes, $1-10 \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}$ would be the typical $\varepsilon_{\max }$ values for Laporte-forbidden $d$-d electronic absorptions. For noncentrosymmetric complexes like tetrahedral complexes a typical $\varepsilon_{\max }$ value for Laporteforbidden $d$ - $d$ electronic absorptions would be $10-1000 \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1} .56$

Figure 3.31: UV-Vis spectra of 3.24a (pink trace) and 3.24b (blue trace).

Figure 3.32: Colours of 3.24a (left, in wet DMF) and 3.24b (right, in dry DMF) in solution.

The extracted $\varepsilon_{\text {max }}$ values from the spectra further indicated that octahedral and tetrahedral complexes existed. Collating the data obtained for both samples, the two structures proposed for $\mathbf{3 . 2 4}$ correlated well with our findings.

After in situ hydrolysis of $\mathbf{3 . 2}$ in $\mathrm{H}_{2} \mathrm{O}$ and MeOH , the addition of an aqueous solution of $\mathrm{Co}(\mathrm{SCN})_{2}$ resulted in a pink solution, which when allowed to stand for several days formed an orange solid. The IR spectrum of this product, $\mathbf{3 . 2 5}$, displayed a $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$stretch at $1635 \mathrm{~cm}^{-1}$ and a corresponding $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$stretch at $1372 \mathrm{~cm}^{-1}$. This gave a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-\nu_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$value of $263 \mathrm{~cm}^{-1}$, which would generally indicate monodentate coordination. However, the relatively low $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$frequency could indicate the presence of non-coordinated carboxylates, since these lower frequencies were a characteristic of our previously synthesised coordination networks with free carboxylates. Broad stretches centred at $3218 \mathrm{~cm}^{-1}$ were also visible in the IR spectrum which indicated the presence of coordinating H-bonded water molecules. ${ }^{175}$ Elemental analysis suggested that the composition of the complex was 1:2 metal to ligand. Therefore, it was proposed that the complex consisted of an octahedral Co(II) metal centre with two
3.2(pytza) ligands coordinating via their pyridine and tetrazole nitrogens and two $\mathrm{H}_{2} \mathrm{O}$ molecules filling the coordination sphere. This structure was recently obtained by Yang et al. from the reaction of $\mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}$ and 5-(2-pyridyl)tetrazole-2-acetic acid under solvothermal conditions. ${ }^{173}$ The crystal structure that they obtained can be seen in Figure 3.33.

Figure 3.33: Crystal structure obtained by Yang et al. for a Co(II) complex of 3.2(pytza). ${ }^{173}$

The data obtained for 3.25 correlated well with that reported by Yang et al., and was in agreement with the crystal structure.

### 3.3.3 EPR Spectral Studies

### 3.3.3.1 EPR Spectroscopy Theory

Electron paramagnetic resonance (EPR) is a branch of spectroscopy in which radiation of microwave frequency is absorbed by molecules, ions or atoms possessing electrons with unpaired spins, hence this non-destructive technique can only be applied to samples having one or more unpaired electrons. ${ }^{176}$ The phenomenon of electron spin resonance spectroscopy can be explained by considering a free electron in space without any outside forces. This electron possesses an intrinsic angular momentum and because this electron is charged, the angular motion of this charged particle generates a magnetic field and therefore possesses a magnetic moment. When this unpaired electron interacts with an applied magnetic field, $B_{0}$, two energy levels of the magnetic moment result. This phenomenon is called the Zeeman effect. The unpaired electron will have a state of lowest energy when the moment of the electron is aligned with the magnetic field $\left(m_{s}=-1 / 2\right)$, and will have a state of highest energy when the moment of the electron is aligned against the magnetic field $\left(\mathrm{m}_{\mathrm{s}}=+1 / 2\right)$ (Figure 3.34).

Figure 3.34: Induction of the spin state energies as a function of the magnetic field $B_{0}$.

The transition energy between the two states is given by Equation 3.2.

$$
\Delta E=g \beta B_{0}=h v \quad \text { Eqn. } 3.2
$$

From the above equation, the $g$ factor can be determined. The magnitude of $g$ contains chemical information on the nature of the bond between the electron and the molecule and the electronic structure of the molecule. The magnitude of $g$ depends on the extent of the spin-orbit coupling, which depends on the size of the nucleus containing the unpaired electron. Therefore, organic free radicals will have a small contribution from spin-orbit coupling, producing $g$ factors very close to the free electron value ( $g_{\mathrm{e}}=2.0023$ ) while the $g$ factors of much larger elements, such as metals, may be significantly different from $g_{\text {e }}$ because of huge contribution from spin-orbit coupling. Since $\beta$ is a constant and the magnitude of $B_{0}$ can be measured, to calculate $g$ the value of $\Delta \mathrm{E}$ must be determined, the energy between the two energy levels. This is done by irradiating the sample with microwaves with a set frequency and sweeping the magnetic field. Absorption of energies will occur when Equation 3.2 is satisfied. The value of $g$ can then be calculated from $v$ in GHz and $B_{0}$ in Gauss using:

$$
\begin{equation*}
g=\frac{h v}{\beta B_{0}} \tag{Eqn. 3.3}
\end{equation*}
$$

where $h=6.626 \times 10^{-34} \mathrm{~J} . \mathrm{s}$ and $\beta=9.274 \times 10^{-28} \mathrm{~J} / \mathrm{G}$. Hence, the energies between the two spin states increases linearly as the magnetic field increases. In conventional spectroscopy like NMR, a constant magnetic field is applied to the sample and the frequency of the electromagnetic radiation is scanned. In EPR spectroscopy however, the electromagnetic
radiation frequency is kept constant and the magnetic field is scanned. A peak in the absorption will occur when the magnetic field tunes to the two spin states so that their energy difference matches the energy of the radiation. The source of radiation in EPR is called a klystron. An X-band klystron has a spectral band width of about 8.8-9.6 GHz. This makes it impossible to continuously vary the wavelength similarly to optical spectroscopy. Therefore, it is necessary to vary the magnetic field, until the quantum of the radar waves fits between the field-induced energy levels. ${ }^{176}$

In a molecule, orbitals are orientated in a certain direction, hence the magnitude of spinorbit coupling is direction dependent, or anisotropic. For every paramagnetic molecule, there exists a unique axis system called the principal axis system. The $g$ factors measured along these axes are called the principal $g$ factors and are labelled $g_{\mathrm{x}}, g_{\mathrm{y}}$ and $g_{\mathrm{z}}$. In the simplest type of EPR spectrum, a metal ion has a totally symmetric environment. Here, the electrons in the different $d$ orbitals have equal interactions in all directions, the orbital moment is equal in all directions and so the total magnetic moment is the same in all directions. When placed in an external field, the magnitude of the total magnetic momentum in the direction of the external field will always be the same. This means it will only have one $g$ factor ( $g_{\mathrm{x}}=g_{\mathrm{y}}=g_{\mathrm{z}}$ ) and only one value of the external field where resonance occurs, thus there will only be one absorption line. This EPR spectrum is said to be isotropic. Figure 3.35 shows an example of a molecule where the paramagnetic metal is coordinated by two equal ligands in the z -direction and four different but equal ligands in both the $x$ - and $y$-directions. As a result the $g$ factor will be different for the situations where the field $B_{0}$ is parallel to the z axis or parallel to either the x or y axes. In a powder sample, the paramagnets are not aligned in a set direction and so are in all possible orientations. Consequently, there are a large number of overlapping absorption lines starting at $B_{z}$ and ending at $B_{\mathrm{x}, \mathrm{y}}$. What is detected is the sum of all these lines. The situation where the x - or y -direction is parallel to $B$ occurs much more frequently than one with its z -axis parallel to $B$. Hence, the total absorption in the $\mathrm{x}, \mathrm{y}$-direction is much larger than in the z-direction. This EPR spectrum is said to show axial symmetry (unique axis that differs from the other two, $g_{\mathrm{x}}=g_{\mathrm{y}} \neq g_{\mathrm{z}}$ ). The last class of EPR spectrum is called rhombic and occurs when all the $g$ factors differ ( $g_{\mathrm{x}} \neq g_{\mathrm{y}} \neq g_{\mathrm{z}}$ ).

Figure 3.35: Dependency of the $g$ factor on the orientation of the molecules in the magnetic field. The consequential EPR spectrum in this particular case is an axial spectrum.

The interaction of an unpaired electron with the nuclear magnetic moment is termed nuclear hyperfine interaction. The resonance condition becomes

$$
h v=g \beta B_{0}+h A m_{l} \quad \text { Eqn. } 3.4
$$

where A is called the hyperfine coupling constant and $m_{l}$ is the magnetic moment quantum number for the nucleus. Since there are $2 l+1$ possible values of $m_{l}\left(m_{l}= \pm l, \pm l-1, \ldots, 0\right)$, the hyperfine interaction terms splits the Zeeman transition into $2 l+1$ lines of equal intensity. The two principal isotopes of copper, ${ }^{63} \mathrm{Cu}$ and ${ }^{65} \mathrm{Cu}$, both have nuclear spins of $3 / 2$ so that the Zeeman line will be split into four lines ( $m_{l}=3 / 2,1 / 2,-1 / 2,-3 / 2$ ). The hyperfine coupling along $g_{z}$ for $\mathrm{Cu}^{2+}$ is always much greater than that along $g_{x}$ or $g_{y}$, resulting in a large splitting of the $g_{\mathrm{z}}$ line with only minor (often unobservable) splitting of $g_{\mathrm{x}}$ or $g_{\mathrm{y}}$.

Finally, for practical purposes, the first derivative spectrum instead of the true absorption is recorded. The $g$ factors are very easy to recognise in these types of spectra as it emphasises rapidly changing features of the spectrum, thus enhancing resolution.

### 3.3.3.2 EPR Spectral Studies on $\mathrm{Cu}(\mathrm{II})$ Compounds

The X-band solid state EPR spectra of 3.8-3.13 were measured in the solid state at room temperature. $\mathrm{Cu}(\mathrm{II})$ has a $\mathrm{d}^{9}$ configuration and has one unpaired electron, hence it has an effective spin of $1 / 2$. The configuration of square pyramidal is characterised by the ground
state $\mathrm{d}_{x^{2}-y^{2}}$. Trigonal bipyramidal is also a five coordinated geometry which is characterised by the ground state $\mathrm{d}_{z}{ }^{2}$. EPR spectra of $\mathrm{Cu}(I I)$ complexes provides a useful method to distinguish between these two general states.

Figure 3.36: Room temperature 9.63 GHz EPR spectrum of a powder sample of 3.8. $\left(g_{x} ; g_{y}\right.$;

$$
\left.g_{\mathrm{z}}\right)=(2.0477 ; 2.0739 ; 2.2586),\left(A_{\mathrm{x}} ; A_{\mathrm{y}} ; A_{\mathrm{z}}\right)=\left(0 ; 0 ; 0: 0009 \mathrm{~cm}^{-1}\right) .
$$

The EPR spectrum for $\mathbf{3 . 8}$ is shown in Figure 3.36. It was observed that the $g_{\mathrm{z}}$ factor is greater than the $g_{\mathrm{x}} \sim g_{\mathrm{y}}$ factors, which in turn is greater than the $g_{\mathrm{e}}$ value. For systems where $g_{\mathrm{z}}>g_{\mathrm{y}}>g_{\mathrm{x}}$, the ratio of $\left(g_{\mathrm{y}}-g_{\mathrm{x}} / g_{\mathrm{z}}-g_{\mathrm{y}}\right.$ ) (called the parameter R) is useful in discriminating between a $\mathrm{d}_{x^{2}-y^{2}}$ and a $\mathrm{d}_{z}{ }^{2}$ ground state. ${ }^{177}$ If R is greater than 1 , then the ground state is $\mathrm{d}_{z}^{2}$. If the ground state is $\mathrm{d}_{x^{2}-y^{2}}$, then the value of R is less than 1 . The EPR spectrum of 3.8 shows the value of R to be less than 1 , thus confirming five coordinate square pyramidal geometry, and the spectrum is said to show axial symmetry. The additional lines observed at 3200 G in the spectrum were attributed to crystalline material in the sample, which were greatly reduced on grinding the sample into a powder, however complete removal of these crystalline particle proved difficult, hence their presence in Figure 3.36.

The EPR spectrum of 3.9 was measured in the solid state at room temperature and can be seen in Figure 3.37. The mononuclear complex showed a relatively simple spectrum indicating axial geometry (i.e. there was a unique axis that differed from the other two, $g_{\mathrm{x}}$ $=g_{\mathrm{y}} \neq g_{\mathrm{z}}$ ). The abstracted $g$ factors show that $g_{\mathrm{z}}>g_{\mathrm{x}} \sim g_{\mathrm{y}}$, indicating that the unpaired electron lies predominantly in the $\mathrm{d}_{x^{2}-y^{2}}$ orbital.

Figure 3.37: Room temperature 9.63 GHz EPR spectrum of a powder sample of 3.9. $\left(g_{x} ; g_{y}\right.$; $\left.g_{z}\right)=(2.066 ; 2.090 ; 2.223)$.

The EPR spectrum of $\mathbf{3 . 1 0}$ (Figure 3.38) was measured in the solid state at room temperature. The spectrum indicated axial geometry as $g_{\mathrm{z}}>g_{\mathrm{x}} \sim g_{\mathrm{y}}$ was fulfilled and this would be expected from the regular geometry seen in the crystal structure of $\mathbf{3 . 1 0}$. Therefore, $\mathrm{d}_{x^{2}-y^{2}}$ was the ground state.

Figure 3.38: Room temperature 9.63 GHz EPR spectrum of a powder sample of 3.10. The experimental and calculated spectrum is indicated with a solid and dashed line, respectively. The calculated spectrum was obtained from our collaborator using a Hamiltonion equation (Appendix B) with the following spin Hamiltonian parameters: ( $g_{\times}$;

$$
\left.g_{\mathrm{y}} ; g_{\mathrm{z}}\right)=(2.070 ; 2.074 ; 2.334),\left(A_{\mathrm{x}} ; A_{\mathrm{y}} ; A_{\mathrm{z}}\right)=\left(0 ; 0 ; 0: 0044 \mathrm{~cm}^{-1}\right) .
$$

The X-band spectrum of $\mathbf{3 . 1 1}$ was measured in the solid state at room temperature and can be seen in Figure 3.39. This dimer showed three different $g$ factors ( $g_{\mathrm{x}} \neq g_{\mathrm{y}} \neq g_{\mathrm{z}}$ ), revealing the rhombic symmetry of the coordination sphere. These signals correspond to the three different main axes $\mathrm{x}, \mathrm{y}$ and z of the magnetic tensor which are all of different
length. This can be seen when examining the crystal structure of 3.11. In this distorted octahedral complex, coordination bond lengths differ greatly ( $\mathrm{Cu}-\mathrm{N}_{\mathrm{pyr}} 2.040 \AA, \mathrm{Cu}-\mathrm{N}_{\text {tet }}$ $2.282 \AA, \mathrm{Cu}-\mathrm{H}_{2} \mathrm{O} 1.965 \AA, \mathrm{Cu}-\mathrm{O}_{\text {monodentate }} 1.939 \AA, \mathrm{Cu}-\mathrm{O}_{\text {bidentate }} 2.765 \AA, \mathrm{Cu}-\mathrm{O}_{\text {bidentate }} 1.940 \AA$ ) therefore the appearance of a rhombic signal is not surprising.

Figure 3.39: Room temperature 9.63 GHz EPR spectrum of a powder sample of 3.11. $\left(g_{x}\right.$; $\left.g_{\mathrm{y}} ; g_{\mathrm{z}}\right)=(2.056 ; 2.124 ; 2.312),\left(A_{\mathrm{x}} ; A_{\mathrm{y}} ; A_{\mathrm{z}}\right)=\left(0 ; 0 ; 0: 0045 \mathrm{~cm}^{-1}\right)$.

The solid state EPR spectrum for $\mathbf{3 . 1 3}$ (Figure 3.40) measured at room temperature again displayed approximate axial symmetry with $g_{\mathrm{z}}>g_{\mathrm{x}} \sim g_{\mathrm{y}}$ which was expected for this octahedral complex, which has a $\mathrm{d}_{x^{2}-y^{2}}$ ground state.

Figure 3.40: Room temperature 9.63 GHz EPR spectrum of a powder sample of 3.13. $\left(g_{\mathrm{xy}} ;\right.$

$$
\left.g_{z}\right)=(2.042 ; 2.555) .
$$

### 3.3.4 Luminescent Properties of CPs

### 3.3.4.1 Overview of Luminescence

Fluorescence spectroscopy is an area of chemistry which encompasses a broad spectrum of concepts and as such will only be covered here in fundamental detail. Luminescence can be defined as the emission of light upon absorption of energy under the condition that the energy source is not heat based. Luminescence is an occurrence whereby the emission of a photon from an electronic excited state of a molecule occurs at a lower energy (longer wavelength) than the wavelength at which the photon was absorbed. ${ }^{178}$ The difference in energy is known as the Stokes shift and can be explained by the Franck-Condon principle. This states that all electronic transitions are vertical, that is, they occur without change in the position of the nuclei. ${ }^{179}$ A direct result of the higher energy potential of the excited state is that the vertical transition for the lowest vibrational energy level of the ground state, $v^{\prime \prime}{ }_{0}$, intersects the excited state at the $v_{n}^{\prime}$ energy level. The excited electron loses energy through non-radiative decay to the lowest vibrational energy level in the excited state: $v^{\prime}{ }_{0}$. The emitted photon originates from a transition $v_{0}$ to $v^{\prime \prime}{ }_{n}$, a point where its vertical transition intersects the ground state potential energy curve. As before, nonradiative decay returns the electron to the lowest vibronic energy level: $v{ }^{\prime \prime}{ }_{0}$. The above transitions are summarised in Figure 3.41. The energy difference between absorption ( $v{ }^{\prime \prime}{ }_{0}$ $\left.\rightarrow v_{n}^{\prime}\right)$ and emission $\left(v_{0}^{\prime} \rightarrow v_{n}^{\prime \prime}\right)$ is the reason why a Stokes shift occurs.

Figure 3.41: Vibrational level of transitions of an electron for both absorption and emission processes. Reprinted with permission. ${ }^{180}$

When a molecule absorbs a photon of energy, a chain of photophysical events occur, including the two main types of luminescence: fluorescence and phosphorescence,
depending on the nature of the excited state. ${ }^{181}$ In the case of fluorescence, a single electron absorbs this energy and undergoes an electronic transition from the singlet ground state $\mathrm{S}_{0}$ to a singlet excited state. This excited electron, arbitrarily denoted $a,\left(S_{a}=\right.$ $+1 / 2$ ) is spin paired with the corresponding electron, denoted $a^{*}$, in the ground state orbital ( $S_{a^{*}}=-1 / 2$ ). This photo-excited electron decays to the lowest vibrational level of the first excited singlet. The phenomenon of fluorescence results when a spin-allowed singletsinglet radiative transition ( $\Delta S=0$ ) from the lowest excited singlet state $S_{1}$ to the ground singlet state $S_{0}$ occurs. The notation of the singlet state originates from the multiplicity formula $\mathrm{M}=2 S+1$, where M is the multiplicity of the state and $S$ the number of unpaired electrons. This process has typical lifetimes in the order of 1 ns . Phosphorescence, in comparison, involves a spin-forbidden radiative transition from the triplet state $\mathrm{T}_{1}$ to the ground state $S_{0}(\Delta S \neq 0)$. Absorption occurs in the same manner as with the fluorescence absorption transition. In phosphorescence however (a process that can be as a long as several seconds), the electron undergoes a change of $\operatorname{spin}\left(S_{a}=+1 / 2\right.$ to $-1 / 2$ ) to the $\mathrm{T}_{1}$ triplet state. This triplet state is slightly lower in energy than the corresponding $\mathrm{S}_{1}$ state (due to Hund's rule). Conversion from the $S_{1}$ state to the $T_{1}$ state (intersystem crossing) becomes possible due to spin-orbit coupling. ${ }^{182}$ A summary of the radiative and non-radiative processes are shown in the Jablonski diagram in Figure 3.42.

Figure 3.42: Jablonski diagram which shows all the possible transitions between electronic states. $\mathrm{S}=$ singlet state, $\mathrm{T}=$ triplet state, IC = internal conversion and ISC = intersystem crossing. ${ }^{179}$

### 3.3.4.2 The Origin of Luminescence in CPs

Fluorescence is commonly observed in aromatic molecules. This is because of the extensive electron delocalisation of the $\pi$ electrons. This extensive $\pi$ system lowers the
energy required for a $\pi \rightarrow \pi^{*}$ transition (the lowest energy transition) and as a result yields a larger wavelength emission band than the corresponding absorption band. In CPs and MOFs, a wide range of $\pi$-conjugated organic molecules are commonly used as linkers. Usually, the fluorescence emission from organic ligands is similar to their emission behaviour in solution, corresponding to the transition from the lowest excited singlet state to the singlet ground state and the transitions are either $\pi \rightarrow \pi^{*}$ or $n \rightarrow \pi^{*}$ in nature. However, the maximum emission wavelength and lifetime of organic linkers in solid MOFs are often different from those of the free molecules. This is because the organic linkers are stabilised within MOFs which reduces the nonradiative decay rate and leads to increased fluorescence intensities, lifetimes and quantum efficiencies. ${ }^{183}$ In addition, these structures are often particularly susceptible to $\pi$-stacking in the solid state, further enhancing their fluorescence properties. In the solid state, molecular interactions can bring lumophores close together, enabling electronic interactions between the lumophores (e.g. ligand to ligand charge transfer (LLCT)).

Luminescence in MOFs is typically based on the linker rather than on the metal (LLCT), but can also involve charge transfer between the metal and linker (metal to ligand charge transfer (MLCT) or ligand to metal charge transfer (LMCT)), metal-based luminescence, metal to metal charge transfer (MMCT) and sometimes guest molecules may contribute to the emission. ${ }^{184}$ Emission from paramagnetic transition-metal complexes is usually not strong because ligand-field transitions ( $d-d$ ) may lead to strong reabsorption and/or quenching of fluorescence generated from the organic molecule, which can occur via electron or energy transfer through the partially filled $d$ orbitals. However, MOFs with transition metal ions without unpaired electrons, especially those having $\mathrm{d}^{10}$ configurations, can yield linker-based highly emissive materials. Metal based luminescence is most often seen when lanthanide ions are incorporated in the framework. These mechanisms are not mutually exclusive and more than one emission pathway can co-exist in a competitive manner with another. ${ }^{184}$

The motivation behind studying metal-organic matrices as luminescent materials lies in their advantages over organic molecular solids. The photophysical properties of organic compounds in the solid state has been a rich area of study and recent work on organic solid-state devices has renewed interest in photoabsorption and emission from thin films, monolayers and matrices of these compounds. ${ }^{185}$ Controlling these ligand-ligand interactions is important for applications that involve charge transport and to obtain tunable emission colours. In molecular solids, the multitude of weak interactions, such as
$\pi$-stacking and hydrogen bonding make it difficult to predict the crystal structure a priori. CPs have a potential advantage in this context in that they offer a degree of predictability to the structure in a defined, crystalline network that can be useful for extracting structure-property relationships. ${ }^{184}$ The presence of both inorganic and organic moieties can provide additional luminescent functionality due to the potential LMCT and MLCT phenomena. This feature has seen CPs investigated for their potential application as inorganic LEDs. ${ }^{186}$ The porosity of some CPs further enable the adsorption of guest molecues which can alter the parent framework's photoemission profile, making them excellent candidates for chemosensing. ${ }^{181}$

### 3.3.4.3 Luminescent Properties of Zn (II) Compounds

The photoluminescence of $\mathrm{d}^{10}$ metal complexes has developed into an attractive research field owing to their potential applications in chemical sensors, photochemistry and inorganic LEDs. ${ }^{181,186}$ The solid state emission spectra of $\mathbf{3 . 1}$ (pytzaH), 3.2 (pytzaH), 3.14, 3.15 and 3.16 (Figure 3.43) were measured at room temperature and are depicted in Figure 3.44. It can be seen that they exhibit fluorescence signals with the emission maxima at 452 nm for the free ligand $\mathbf{3 . 1}$ (pytzaH), 436 nm for the free ligand $\mathbf{3 . 2}$ (pytzaH), and 434, 444 and 438 nm for the complexes 3.14, $\mathbf{3 . 1 5}$ and $\mathbf{3 . 1 6}$ respectively, with $\lambda_{\mathrm{ex}}=350$ nm . Compared to the spectrum of the free ligand $\mathbf{3 . 1}$ (pytzaH), complexes $\mathbf{3 . 1 4}$ and $\mathbf{3 . 1 5}$ exhibited slight blue shifts of emission lengths 18 and 8 nm , respectively. The quenching in emission that was observed in $\mathbf{3 . 1 4}$ is tentatively attributed to the tetrazole and pyridine rings been in a rigid non-planar arrangement due to the coordination of $\mathrm{Zn}(\mathrm{II})$, which concomitantly would decrease the conjugative effect for the ligand. The free ligand 3.2 (pytzaH) exhibited weak emission bands. Compared to this spectrum, $\mathbf{3 . 1 6}$ was similar in terms of position but an obvious increase in emission was observed. This emission band is mainly due to an intraligand emission state, which is characteristic of fluorescent emissions for $\mathrm{Zn}(\mathrm{II})$ complexes with N -donor aromatic ligands. ${ }^{187,188}$ The intensity increase of the luminescence for the complexes may be attributed to the chelation of the ligand to the metal centre, which increases the rigidity of the ligands and reduces the non-radiative relaxation process (via vibrational motions). ${ }^{146,188} \mathrm{Cu}(\mathrm{II})$ complexes 3.8-3.13 did not exhibit any emissive properties, which was expected as paramagnetic metal ions have low $d-d$ transitions which can relax the excitation energy through a non-radiative pathway, thus quenching luminescence. ${ }^{181}$ The marked difference in the fluorescence intensities observed for the free ligands is tentatively ascribed to the co-planarity of the $\mathrm{N}-1$ substituted ligand. In the crystal structure of $\mathbf{3 . 1}$ (Figure 3.12), this co-planar behaviour
was observed and it would be presumed that this would also manifest itself in the structure of the corresponding free acid $\mathbf{3 . 1}$ (pytzaH). The N-2 substituted regioisomer however, may not be capable of adopting this co-planar conformation in the solid state and could disrupt the ligand to ligand transitions if not stacked appropriately. This of course, could be confirmed by undertaking X-ray crystallographic analysis of the crystal structures of both carboxylic acid derivatives $\mathbf{3 . 1}$ (pytzaH) and $\mathbf{3 . 2}$ (pytzaH).

### 3.4 Conclusions

For the purpose of investigating the ability of ester and carboxylate functionalised pyridyl tetrazoles to form coordination polymers, $\mathbf{3 . 1}$ and 3.2 were synthesised utilising methods previously established. These ligands were then reacted with $\mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ and displayed interesting coordination chemistry as the position of the alkylation site appeared to have some effect on how the ligand coordinated to the metal centre. These results hinted at the diversity that could be obtained when these regioisomers would be used in coordination polymer synthesis.

Ligands 3.1 and 3.2 were hydrolysed in situ to form carboxylates which, in combination with the pyridyl tetrazole binding sites, afforded diverse structures on complexation to metal(II) ions. Regiochemical differences between the linkers played a key role in the formation of these structures and furthermore, solvent also had an affect on what structures were formed. In MeOH , polymeric coordination polymers tended to form whereas when employing water as reaction solvent, hydrogen bonded coordination networks were inclined to form by virtue of coordinating water molecules. It also became apparent that the level of hydration of the metal salt may have provided enough water for these hydrogen bonded networks to form, as seen in the cases where $\mathrm{NiCl}_{2} .6 \mathrm{H}_{2} \mathrm{O}$ was employed.

X-band EPR spectroscopy was carried out on powdered samples at room temperature on $\mathrm{Cu}(\mathrm{II})$ structures and revealed approximate axial symmetry apart from one complex, 3.11, which showed a rhombic EPR signal. These signals were in agreement with the crystal structures obtained and were typical of $\mathrm{Cu}(\mathrm{II})$ complexes with a $\mathrm{d}_{x}{ }^{2}-y^{2}$ ground state.

Solid state fluorescence spectroscopy was carried out on Zn (II) compounds and their corresponding free acid ligands at room temperature. The emission spectra suggest that the complexes formed could be efficient light emitting materials for potential applications. Investigations will have to be carried out in order to elucidate the reason that the two free acid ligands possessed such different emission profiles. Until such investigations are undertaken, we postulate that the packing of the structures in the solid state could contribute to these differences.

Future work would involve the use of other $\mathrm{d}^{10}$ metal ions in the synthesis of these coordination polymers in order to investigate their luminescence properties and to
investigate the thermal stabilities of the compounds formed in this chapter. Furthermore, as coordination polymers with low dimensionality were formed in this work, we intended on developing the linkers discussed in this chapter in order to achieve high dimensional, potentially porous materials. The attempts at addressing this issue is the subject of Chapter 4.

### 3.5 Experimental

### 3.5.1 Instrumentation

${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR ( $\delta \mathrm{ppm} ; J \mathrm{~Hz}$ ) spectra were recorded on a Bruker Avance 300 MHz NMR spectrometer using saturated $\mathrm{CDCl}_{3}$ or $d_{6}$-DMSO solutions with a $\mathrm{SiMe}_{4}$ reference, with resolutions of 0.18 Hz and 0.01 ppm , respectively. Infrared spectra ( $\mathrm{cm}^{-1}$ ) were recorded as KBr discs or liquid films between NaCl plates using a Perkin Elmer System 2000 FT-IR spectrometer. Solution UV-Vis spectra were recorded using HPLC grade solvents using a Unicam UV 540 spectrometer. Melting point analyses were carried out using a Stewart Scientific SMP 1 melting point apparatus and are uncorrected. Electrospray (ESI) mass spectra were collected on an Agilent Technologies 6410 Time of Flight LC/MS. Compounds were dissolved in acetonitrile:water (1:1) solutions containing $0.1 \%$ formic acid, unless otherwise stated. The interpretation of mass spectra was made with the help of the program "Agilent Masshunter Workstation Software". Magnetic susceptibility measurements were carried out at room temperature using a Johnson Matthey Magnetic Susceptibility Balance with $\left[\mathrm{HgCo}(\mathrm{SCN})_{4}\right]$ as reference. EPR spectra were recorded on a Bruker Elexsys E500 spectrometer, operated at the X-band and equipped with an Oxford Instruments cryostat. Solid state UV-Vis measurements were carried out in the Synthetic Bioinorganic Chemistry Laboratory of the University of Crete and were performed on a Perkin Elmer Lambda 950 UV/Vis spectrometer. Solid state fluorescence spectra were also carried out in this laboratory and were recorded on a Jobin-Yvon Horiba, Fluoro Max-P (SPEX) fluorescence spectrometer, with excitation from a cw Xenon arc lamp. Microanalyses were carried out at the Microanalytical Laboratory of the National University of Ireland Maynooth, using a Thermo Finnigan Elementary Analyzer Flash EA 1112. The results were analysed using the Eager 300 software. All crystal structures resulting from this work were solved by Dr. John Gallagher (Dublin City University) using an Oxford Diffraction Gemini-S Ultra diffractometer at 294(1) K. Structures were solved using the shelxs97 direct methods program. Molecular diagrams were generated using Mercury software. Starting materials were commercially obtained and used without further purification. Solvents used were of HPLC grade.
Caution! Nitrogen-rich compounds such as tetrazole derivatives are used as components for explosive mixtures. In our laboratory, the reactions described were run on a few gram scale, and no problems were encountered. However, great caution should be exercised when heating or handling compounds of this type.

### 3.5.2 Synthesis of 3.1 and 3.2

To 2.5 ( $2.00 \mathrm{~g}, 13.60 \mathrm{mmol}$ ) dissolved in MeCN ( 60 mL ) was added $\mathrm{K}_{2} \mathrm{CO}_{3}(3.76 \mathrm{~g}, 27.20$ $\mathrm{mmol})$. The resulting solution was heated to reflux for 30 min and to the hot solution was added ethyl bromoacetate ( $2.27 \mathrm{~g}, 13.60 \mathrm{mmol}$ ). The reaction mixture was then stirred at reflux temperature for a further 24 h . After cooling, the reaction mixture was filtered and the filtrate was concentrated under reduced pressure to afford an oil, which was purified by column chromatography on silica gel (at a ratio of Pet. Ether:EtOAc, 1:2). This gave products 3.1 and 3.2.

### 3.5.2.1 Ethyl 2-(5-(pyridin-2-yl)-1H-tetrazol-1-yl)acetate (3.1)

Orange solid ( 0.70 g, 22\%). m.p. 53-55 ${ }^{\circ} \mathrm{C}$. IR (KBr): $v=3015,2989,2970,1748,1591$, 1538, 1474, 1437, 1378, 1274, 1251, 1228, 1117, 1019, 809, 751, $728 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.63-8.66(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 8.41-8.44(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 7.88-7.94(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H})$, 7.41-7.46 (m, 1 H, pyr-H), 5.74 (s, $2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{~N}$ ), $4.19\left(\mathrm{q}, 2 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{OCH}_{2}\right.$ ), 1.18 (t, $3 \mathrm{H}, J=$ $\left.7.1 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=165.9(\mathrm{C}=0), 152.1\left(\mathrm{CN}_{4}\right), 149.2,144.6,137.6$, 125.4, 124.1, 62.1, $51.1\left(\mathrm{CH}_{2} \mathrm{~N}\right), 14.0 \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{10} \mathrm{H}_{12} \mathrm{~N}_{5} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}]^{+}$ 234.0986, found 234.0983 .

### 3.5.2.2 Ethyl 2-(5-(pyridin-2-yl)-2H-tetrazol-2-yl)acetate (3.2)

Cream solid ( $0.74 \mathrm{~g}, 23 \%$ ). m.p. $94-96^{\circ} \mathrm{C}$. IR (KBr): $v=3001,2958,1745,1596,1520$, 1467, 1417, 1368, 1345, 1231, 1051, 1032, 882, 797, $737 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.78-$ $8.80(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 8.26-8.29(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 7.85-7.90(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 7.39-7.44(\mathrm{~m}, 1$ H, pyr-H), $5.50\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{~N}\right), 4.28\left(\mathrm{q}, 2 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{OCH}_{2}\right), 1.28\left(\mathrm{t}, 3 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{3}\right)$ ppm. ${ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=165.2(\mathrm{C}=0), 164.8\left(\mathrm{CN}_{4}\right), 150.3,146.5,137.1,125.0,122.5$, 62.7, $53.5\left(\mathrm{CH}_{2} \mathrm{~N}\right), 14.0 \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{10} \mathrm{H}_{12} \mathrm{~N}_{5} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}]^{+} 234.0986$, found 234.0979.

### 3.5.3 Synthesis of 3.1 (pytzaH) and 3.2 (pytzaH)

3.1 or 3.2 ( $0.10 \mathrm{~g}, 0.43 \mathrm{mmol}$ ) were dissolved in EtOH ( 20 mL ). $10 \mathrm{M} \mathrm{NaOH}(0.1 \mathrm{~mL})$ was added to the solution and the resulting suspension was heated to reflux for 30 min . The solution was allowed to cool and the solid was filtered. The solid was dissolved in deionised $\mathrm{H}_{2} \mathrm{O}(1 \mathrm{~mL})$ and 6 M HCl was added dropwise until a precipitate formed ( pH 3 ). The solid was filtered and dried.

### 3.5.3.1 2-(5-(pyridin-2-yl)-1H-tetrazol-1-yl)acetic acid (3.1(pytzaH))

White solid ( 0.06 g, $68 \%$ ). m.p. $195-200^{\circ} \mathrm{C}$. IR (KBr): $v=3460,3030,2849,1724,1590$, 1473, 1438, 1399, 1354, 1293, 1261, 1248, 1129, 1097, 1011, 994, 814, 799, 729, 656, $622,487 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.65-8.68(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 8.41-8.45(\mathrm{~m}, 1 \mathrm{H}$, pyr-H), 7.91-7.97 (m, 1 H, pyr-H), 7.45-7.49 (m, 1 H, pyr-H), 5.78 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{~N}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=168.8(\mathrm{C}=0), 152.1\left(\mathrm{CN}_{4}\right), 149.2,144.2,137.9,125.7,124.4,50.7\left(\mathrm{CH}_{2} \mathrm{~N}\right) \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{~N}_{5} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}]^{+}$206.0673, found 206.0674.

### 3.5.3.2 2-(5-(pyridin-2-yl)-2H-tetrazol-2-yl)acetic acid (3.2(pytzaH))

White solid ( $0.05 \mathrm{~g}, 62 \%$ ). m.p. $185-186^{\circ} \mathrm{C}$. IR (KBr): $v=3441,2997,2955,1713,1604$, $1434,1348,1260,1206,1166,1058,1022,896,825,803,749,638,431 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(d_{6}{ }^{-}\right.$ DMSO): $\delta=8.75-8.76(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 8.15-8.17(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 8.00-8.05(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H})$, 7.55-7.59 (m, $1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}$ ), $5.78\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{~N}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR ( $d_{6}$-DMSO): $\delta=167.3$ ( $\mathrm{C}=\mathrm{O}$ ), $164.2\left(\mathrm{CN}_{4}\right), 150.2,145.9,137.6,125.3,122.4,54.8\left(\mathrm{CH}_{2} \mathrm{~N}\right) \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{~N}_{5} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}]^{+}$206.0673, found 206.0673.

Data obtained agrees with that reported in the literature. ${ }^{189}$

### 3.5.4 Metal Complexation Reactions

### 3.5.4.1 Metal Complexes of Ester Derivatives 3.1 and 3.2

### 3.5.4.1.1 $\quad\left[\mathrm{Cu}(3.1) \mathrm{Cl}_{2}\right]_{2}(3.8)$

A solution of $\mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(0.15 \mathrm{~g}, 0.86 \mathrm{mmol})$ in $\mathrm{MeOH}(20 \mathrm{~mL})$ was added to a solution of $3.1(0.20 \mathrm{~g}, 0.86 \mathrm{mmol})$ in $\mathrm{MeOH}(20 \mathrm{~mL})$. The resulting solution was heated to reflux for 2 h. The solution was then allowed to stand at room temperature for several days whereupon green crystals formed. Green crystals ( $0.12 \mathrm{~g}, 39 \%$ ). $\mathrm{C}_{20} \mathrm{H}_{22} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{4}$ : calcd. C 32.65, H 3.02, N 19.05\%; found C 32.24, H 2.88, N 18.27\%. IR (KBr): $v=3101,2978$, 2947, 1749, 1616, 1556, 1481, 1456, 1373, 1297, 1261, 1230, 1111, 1009, 870, 787, 749 $\mathrm{cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 872 \mathrm{~nm}, \varepsilon=89 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 1.67 B.M.

### 3.5.4.1.2 $\left[\mathrm{Cu}(3.2) \mathrm{Cl}_{2}\right](3.9)$

A solution of $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}(0.15 \mathrm{~g}, 0.86 \mathrm{mmol})$ in $\mathrm{MeOH}(20 \mathrm{~mL})$ was added to a solution of $3.2(0.20 \mathrm{~g}, 0.86 \mathrm{mmol})$ in $\mathrm{MeOH}(20 \mathrm{~mL})$. The resulting solution was heated to reflux for 2 h. The solution was then allowed to stand at room temperature for several days whereupon blue crystals formed. Blue crystals ( $0.15 \mathrm{~g}, 58 \%$ ). $\mathrm{C}_{20} \mathrm{H}_{22} \mathrm{Cl}_{2} \mathrm{CuN}_{10} \mathrm{O}_{4}$ : calcd. C 39.96, H 3.69, N $23.31 \%$; found C 38.99, H 3.63, N 22.76\%. IR (KBr): $v=3005,2984,2967$, $1749,1611,1450,1388,1368,1283,1214,1018,875,799,756 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 800 \mathrm{~nm}$, $\varepsilon=61 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.17 B.M.

### 3.5.4.2 Reactions of in situ Generated 3.1(pytza) and 3.2(pytza) With Metal Salts

### 3.5.4.2.1 $[\mathrm{Cu}(3.1 \mathrm{pytza})]_{\mathrm{n}}(3.10)$

$\mathrm{NaOH}(0.01 \mathrm{~g}, 0.43 \mathrm{mmol})$ in deionised $\mathrm{H}_{2} \mathrm{O}(1 \mathrm{~mL})$ was added to a solution of $3.1(0.10 \mathrm{~g}$, $0.43 \mathrm{mmol})$ in $\mathrm{MeOH}(10 \mathrm{~mL})$. The resulting solution was heated to reflux for 1 h . After this time, $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}(0.07 \mathrm{~g}, 0.43 \mathrm{mmol})$ was added, then cooled to room temperature and filtered. The blue solid obtained was dissolved in $\mathrm{H}_{2} \mathrm{O}$ and by slow evaporation, blue crystals of the product suitable for X-ray crystallography were obtained. $\mathrm{C}_{16} \mathrm{H}_{12} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{4}$ : calcd. C 30.44, H $1.92, \mathrm{~N} 22.20 \%$; found C 30.68 , H $2.24, \mathrm{~N} 22.41 \%$. IR (KBr): $v=1651$, 1614, 1587, 1471, 1456, 1435, 1392, 1312, 1250, 1123, 926, 814, 793, 745, $730 \mathrm{~cm}^{-1} . \lambda_{\max }$ $\left(\mathrm{H}_{2} \mathrm{O}\right) 656 \mathrm{~nm}, \varepsilon=23 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.29 B.M.

### 3.5.4.2.2 $\quad\left[\mathrm{Cu}(3.1 \text { pytza })_{2} \mathrm{H}_{2} \mathrm{O}\right]_{2}(3.11)$

$3.1(0.20 \mathrm{~g}, 0.86 \mathrm{mmol})$ was dissolved in a mixture of deionised $\mathrm{H}_{2} \mathrm{O}(10 \mathrm{~mL})$ and $\mathrm{MeOH}(1$ $\mathrm{mL}) . \mathrm{NaOH}(0.03 \mathrm{~g}, 0.86 \mathrm{mmol})$ in deionised $\mathrm{H}_{2} \mathrm{O}$ was added to this mixture and the solution was heated to reflux for $1 \mathrm{~h} . \mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}(0.14 \mathrm{~g}, 0.86 \mathrm{mmol})$ was added and the resulting solution was allowed to stand for several days whereupon blue block crystals formed. Blue crystals ( $0.13 \mathrm{~g}, 65 \%$ ). $\mathrm{C}_{16} \mathrm{H}_{14} \mathrm{CuN}_{10} \mathrm{O}_{5}$ : calcd. C 39.21, H 2.88, $\mathrm{N} \mathrm{28.60} \mathrm{\% ;}$ found C 40.09, H 2.55, N 28.95\%. IR (KBr): $v=3133,3001,2984,1650,1609,1537,1471$, $1458,1434,1359,1311,1300,1243,1166,1112,808,790,752 \mathrm{~cm}^{-1} . \lambda_{\max }\left(\mathrm{H}_{2} \mathrm{O}\right) 748 \mathrm{~nm}, \varepsilon$ $=10 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.02 B.M.

### 3.5.4.2.3 $\quad[\mathrm{Cu}(3.2 \text { pytza }) \mathrm{OH}]_{\mathrm{n}}(3.12)$

$\mathrm{NaOH}(0.01 \mathrm{~g}, 0.43 \mathrm{mmol})$ in deionised $\mathrm{H}_{2} \mathrm{O}$ was added to a solution of $3.2(0.10 \mathrm{~g}, 0.43$ $\mathrm{mmol})$ in $\mathrm{MeOH}(10 \mathrm{~mL})$. The resulting solution was refluxed for 1 h , in which time a white precipitate had formed. After this time, $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}(0.07 \mathrm{~g}, 0.43 \mathrm{mmol})$ was added and the resulting mixture was cooled to room temperature and filtered. Pale green solid 0.11 g , $92 \%) . \mathrm{C}_{8} \mathrm{H}_{7} \mathrm{CuN}_{5} \mathrm{O}_{3}$ : calcd. C $33.75, \mathrm{H} 2.48$, N $24.60 \%$; found C 33.56 , H $2.49, \mathrm{~N} 24.17 \%$. IR $(\mathrm{KBr}): v=3414,3262,3097,1661,1636,1451,1416,1384,1344,1287,1217,1067,821$, 800, 801, 759, 730, 684, $673 \mathrm{~cm}^{-1}$. $\lambda_{\max }$ (DMSO) $496 \mathrm{~nm}, \varepsilon=148 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.50 B.M.

### 3.5.4.2.4 $\quad\left[\mathrm{Cu}(3.2 \text { pytza })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (3.13)

$3.2(0.10 \mathrm{~g}, 0.43 \mathrm{mmol})$ was dissolved in a mixture of deionised $\mathrm{H}_{2} \mathrm{O}(10 \mathrm{~mL})$ and $\mathrm{MeOH}(1$ $\mathrm{mL}) . \mathrm{NaOH}\left(0.01 \mathrm{~g}, 0.43 \mathrm{mmol}\right.$ ) in deionised $\mathrm{H}_{2} \mathrm{O}$ was added to this mixture and the solution was heated to reflux for $1 \mathrm{~h} . \mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}(0.07 \mathrm{~g}, 0.43 \mathrm{mmol})$ in deionised $\mathrm{H}_{2} \mathrm{O}$ was added and the resulting solution was cooled slowly. The resulting pale blue crystals were filtered and air dried. Pale blue crystals ( 0.09 g , $90 \%$ ). $\mathrm{C}_{16} \mathrm{H}_{16} \mathrm{CuN}_{10} \mathrm{O}_{6}$ : calcd. C 37.82, H 3.18, N 27.58\%; found C 37.87, H 3.45, N 26.71\%. IR (KBr): $v=3195,3022,1728,1628$, $1614,1465,1453,1420,1376,1289,1221,1174,1164,1066,1031,826,797,731 \mathrm{~cm}^{-1}$. $\lambda_{\text {max }}\left(\mathrm{H}_{2} \mathrm{O}\right) 760 \mathrm{~nm}, \varepsilon=33 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 1.80 B.M.

### 3.5.4.2.5 $\quad[\mathrm{Zn}(3.1 \mathrm{pytza})] \mathrm{n}(3.14)$

A solution of 3.1 ( $0.10 \mathrm{~g}, 0.43 \mathrm{mmol}$ ) and $\mathrm{NaOH}(0.02 \mathrm{~g}, 0.43 \mathrm{mmol})$ in $\mathrm{MeOH}(18 \mathrm{~mL})$ was heated to reflux for 1 h . After this time, a solution of $\mathrm{ZnCl}_{2}(0.06 \mathrm{~g}, 0.43 \mathrm{mmol})$ in MeOH (5 mL ) was added to the reaction. The solution was then allowed to stand at room
temperature for several days. The solids formed were filtered off and washed with MeOH . White solid ( $0.05 \mathrm{~g}, 50 \%$ ). $\mathrm{C}_{16} \mathrm{H}_{12} \mathrm{~N}_{10} \mathrm{O}_{4} \mathrm{Zn}$ : calcd. C 40.57, H 2.55, N $29.57 \%$; found C 41.03, H 3.54, N 29.51\%. IR (KBr): v = 3435, 3004, 1650, 1610, 1474, 1462, 1435, 1365, 1314, 1301, 1248, 1165, 1010, 900, 808, 794, 727, 702, $679 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO): $\delta=8.68-$ 8.69 (m, 1 H, pyr-H), 8.23-8.26 (m, 1 H, pyr-H), 8.02-8.07 (m, 1 H, pyr-H), 7.55-7.59 (m, 1 H, pyr-H), 5.53 (s, $2 \mathrm{H} \mathrm{CH}_{2} \mathrm{~N}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $d_{6}$-DMSO): $\delta=170.0$ ( $\mathrm{C}=0$ ), 152.4 ( $\mathrm{CN}_{4}$ ), 150.1, 144.8, 138.5, 126.1, 124.2, $52.2\left(\mathrm{CH}_{2} \mathrm{~N}\right)$ ppm.

### 3.5.4.2.6 [Zn(3.1pytza) $\left.2\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (3.15)

A solution of $3.1(0.10 \mathrm{~g}, 0.43 \mathrm{mmol})$ and $\mathrm{NaOH}(0.02 \mathrm{~g}, 0.43 \mathrm{mmol})$ in deionised $\mathrm{H}_{2} \mathrm{O}(20$ $\mathrm{mL})$ was heated under reflux for 1 h . After this time, a solution of $\mathrm{ZnCl}_{2}(0.06 \mathrm{~g}, 0.43 \mathrm{mmol})$ in $\mathrm{H}_{2} \mathrm{O}(5 \mathrm{~mL})$ was added to the reaction and heated under reflux for 1 h . The solution was then allowed to stand at room temperature for several days. The solids formed were filtered off and washed with deionised $\mathrm{H}_{2} \mathrm{O}$. White crystals ( $0.03 \mathrm{~g}, 28 \%$ ). $\mathrm{C}_{16} \mathrm{H}_{16} \mathrm{~N}_{10} \mathrm{O}_{6} \mathrm{Zn}$ : calcd. C 37.70 , H 3.16, N $27.48 \%$; found C 36.93 , H 4.06, N $28.29 \%$. IR (KBr): $v=3415$, 3126, 3004, 1650, 1610, 1474, 1462, 1364, 1301, 1247, 1165, 1010, 900, 808, 793, 750, $727,702,679 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO): $\delta=8.70-8.72(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 8.22-8.25(\mathrm{~m}, 1 \mathrm{H}$, pyr-H), 8.00-8.08 (m, 1 H, pyr-H), 7.55-7.57 (m, $1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}$ ), 5.48 (s, $2 \mathrm{H} \mathrm{CH}_{2} \mathrm{~N}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $d_{6}$-DMSO): $\delta=166.3$ (C=0), $151.9\left(\mathrm{CN}_{4}\right), 149.6,144.5,137.9,125.5,123.7,51.0$ $\left(\mathrm{CH}_{2} \mathrm{~N}\right)$ ppm.

### 3.5.4.2.7 $\quad\left[\mathrm{Zn}_{2}(3.2 \mathrm{pytza})_{2}\left(\mathrm{OCH}_{3}\right)_{2}\right]_{\mathrm{n}}(3.16)$

A solution of $3.2(0.10 \mathrm{~g}, 0.43 \mathrm{mmol})$ and $\mathrm{NaOH}(0.01 \mathrm{~g}, 0.43 \mathrm{mmol})$ in $\mathrm{MeOH}(10 \mathrm{~mL})$ was heated under reflux for 1 h . After this time, $\mathrm{ZnCl}_{2}(0.06 \mathrm{~g}, 0.43 \mathrm{mmol})$ was added to the reaction. The resulting clear solution was allowed to stand for several days and the solids formed were filtered. White crystalline solid ( $0.04 \mathrm{~g}, 31 \%$ ). $\mathrm{C}_{18} \mathrm{H}_{18} \mathrm{~N}_{10} \mathrm{O}_{6} \mathrm{Zn}_{2}$ : calcd. C 35.96, H 3.02, N $23.30 \%$; found C 35.81, H 3.19, N $22.93 \%$. IR (KBr): $v=3523,3423,3090,3005$, 1645, 1611, 1451, 1417, 1383, 1290, 1222, 1145, 1064, 1022, 918, 822, 808, 732, 680, 586 $\mathrm{cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO): $\delta=8.72-8.75(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 8.12-8.16(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 7.97-$ 8.03 (m, 1 H, pyr-H), $7.52-7.57(\mathrm{~m}, 1 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 5.44\left(\mathrm{~s}, 2 \mathrm{H} \mathrm{CH}_{2} \mathrm{~N}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR ( $d_{6}-$ DMSO): $\delta=168.9$ (C=O), $163.7\left(\mathrm{CN}_{4}\right), 150.1,146.2,137.6,125.1,122.2,55.3$ ( $\mathrm{CH}_{2}$-tet), 48.5 $\left(\mathrm{OCH}_{3}\right) \mathrm{ppm}$.

### 3.5.4.2.8 $\quad\left[\mathrm{Zn}(3.2 \text { pytza })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (3.17)

A solution of $3.2(0.10 \mathrm{~g}, 0.43 \mathrm{mmol})$ and $\mathrm{NaOH}(0.01 \mathrm{~g}, 0.43 \mathrm{mmol})$ in $\mathrm{H}_{2} \mathrm{O}(10 \mathrm{~mL})$ was heated under reflux for 1 h . After this time, $\mathrm{ZnCl}_{2}(0.06 \mathrm{~g}, 0.43 \mathrm{mmol})$ was added to the reaction. The solution was allowed to stand at room temperature for several days. Clear block crystals formed which were filtered and washed with deionised $\mathrm{H}_{2} \mathrm{O}$. White crystals ( $0.05 \mathrm{~g}, 50 \%$ ). $\mathrm{C}_{16} \mathrm{H}_{16} \mathrm{~N}_{10} \mathrm{O}_{6} \mathrm{Zn}$ : calcd. C 37.70, H 3.16, N 27.48\%; found C 37.76, H 3.07, N $27.04 \%$. IR (KBr): $v=3419,3236,3025.2867,1638,1614,1547,1456,1417,1373,1290$, 1226, 1145, 1066, 1050, 1031, 929, 901, 827, 801, 757, 731, 700, $685 \mathrm{~cm}^{-1}$. Solid was insoluble in common deuterated solvents.

Data obtained matched that reported in literature. ${ }^{174}$

### 3.5.4.2.9 $\quad\left[\mathrm{Ni}(3.1 \text { pytza) }]_{\mathrm{n}}(3.18)\right.$

3.1 ( $0.10 \mathrm{~g}, 0.43 \mathrm{mmol}$ ) was dissolved in $\mathrm{MeOH} . \mathrm{NaOH}(0.01 \mathrm{~g}, 0.43 \mathrm{mmol}$ ) in deionised $\mathrm{H}_{2} \mathrm{O}$ was added to the solution and this was refluxed for 1 h . After this time $\mathrm{NiCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ ( $0.10 \mathrm{~g}, 0.43 \mathrm{mmol}$ ) in MeOH was added to the solution and the resulting precipitate was filtered off and washed with MeOH. Blue powder ( $0.07 \mathrm{~g}, 62 \%$ ). $\mathrm{C}_{8} \mathrm{H}_{6} \mathrm{~N}_{5} \mathrm{NiO}_{2}$ : calcd. C 36.55, H 2.30, N 26.64\%; found C 35.80, H 2.71, N 25.75\%. IR (KBr): $v=3401,3125,1646,1479$, 1463, 1367, 1304, 1253, 1165, 1113, 1012, 902, 810, 792, 752, 727, 702, 685, 641, 590 $\mathrm{cm}^{-1}$. Magnetic moment: 3.22 B.M.

### 3.5.4.2.10 [ $\mathrm{Ni}(3.1$ pytza)]n (3.19)

A solution of $3.1(0.10 \mathrm{~g}, 0.43 \mathrm{mmol})$ and $\mathrm{NaOH}(0.01 \mathrm{~g}, 0.43 \mathrm{mmol})$ in deionised $\mathrm{H}_{2} \mathrm{O}(15$ $\mathrm{mL})$ was heated to reflux for 1 h . After this time, $\mathrm{NiCl}_{2} .6 \mathrm{H}_{2} \mathrm{O}(0.10 \mathrm{~g}, 0.43 \mathrm{mmol})$ in $\mathrm{H}_{2} \mathrm{O}$ was added and the resulting green solution was allowed to stand at room temperature for several weeks. The solids formed were filtered off and washed with deionised $\mathrm{H}_{2} \mathrm{O}$. Pale blue powder ( $0.04 \mathrm{~g}, 36 \%$ ). $\mathrm{C}_{8} \mathrm{H}_{6} \mathrm{~N}_{5} \mathrm{NiO}_{2}$ : calcd. C $36.55, \mathrm{H} 2.30, \mathrm{~N} 26.64 \%$; found C $37.42, \mathrm{H}$ 2.58, $\mathrm{N} 25.94 \%$. IR (KBr): $v=3401,3123,1643,1478,1464,1365,1303,1253,1165,113$, $1012,901,810,792,752,727,702,684,641,590 \mathrm{~cm}^{-1}$. Magnetic moment: 3.17 B.M.

### 3.5.4.2.11 $\left[\mathrm{Ni}(3.2 \text { pytza })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (3.20)

A solution of $3.2(0.20 \mathrm{~g}, 0.86 \mathrm{mmol})$ and $\mathrm{NaOH}(0.03 \mathrm{~g}, 0.86 \mathrm{mmol})$ in $\mathrm{MeOH}(15 \mathrm{~mL})$ was heated to reflux for 1 h . After this time $\mathrm{NiCl}_{2} .6 \mathrm{H}_{2} \mathrm{O}(0.20 \mathrm{~g}, 0.86 \mathrm{mmol})$ in MeOH was added and the resulting green solution was allowed to stand at room temperature for 1 week.

The blue solid that formed was filtered and washed with MeOH . Blue crystalline solid ( $0.09 \mathrm{~g}, 42 \%$ ). $\mathrm{C}_{16} \mathrm{H}_{16} \mathrm{~N}_{10} \mathrm{NiO}_{2}$ : calcd. C 38.20 , H 3.21, N $27.84 \%$; found C 37.25 , H 3.39, N 27.53\%. IR (KBr): $v=3234,3026,1630,1457,1418,1373,1292,1230,1165,1031,907$, 829, 801, 732, 699, 678, $643 \mathrm{~cm}^{-1}$. Magnetic moment: 2.96 B.M.

### 3.5.4.2.12 $\left[\mathrm{Ni}(3.2 \text { pytza })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (3.21)

A solution of $3.2(0.20 \mathrm{~g}, 0.86 \mathrm{mmol})$ and $\mathrm{NaOH}(0.03 \mathrm{~g}, 0.86 \mathrm{mmol})$ in deionised $\mathrm{H}_{2} \mathrm{O}(15$ $\mathrm{mL})$ was heated to reflux for 1 h . After this time $\mathrm{NiCl}_{2} .6 \mathrm{H}_{2} \mathrm{O}(0.20 \mathrm{~g}, 0.86 \mathrm{mmol})$ in deionised $\mathrm{H}_{2} \mathrm{O}$ was added and the resulting green solution was allowed to stand at room temperature for 1 week. The blue solid that formed was filtered and washed with deionised $\mathrm{H}_{2} \mathrm{O}$. Blue crystalline solid ( $0.11 \mathrm{~g}, 51 \%$ ). $\mathrm{C}_{16} \mathrm{H}_{16} \mathrm{~N}_{10} \mathrm{NiO}_{2}$ : calcd. C $38.20, \mathrm{H} 3.21, \mathrm{~N}$ 27.84\%; found C 37.66, H 2.48, N 27.72\%. IR (KBr): $v=3238,3027,2978,1631,1553$, 1458, 1372, 1292, 1231, 1166, 1031, 907, 828, 801, 732, 699, 682, 644, 575, $426 \mathrm{~cm}^{-1}$. Magnetic moment: 3.12 B.M.

### 3.5.4.2.13 [Co(3.1pytza)]n (3.22)

3.1 ( $0.10 \mathrm{~g}, 0.43 \mathrm{mmol}$ ) was dissolved in $\mathrm{MeOH}(9 \mathrm{~mL})$. NaOH in $\mathrm{H}_{2} \mathrm{O}(0.01 \mathrm{~g}, 0.43 \mathrm{mmol})$ was added to this solution and refluxed for $1 \mathrm{~h} . \mathrm{Co}(\mathrm{SCN})_{2}(0.08 \mathrm{~g}, 0.43 \mathrm{mmol})$ in MeOH was added to the solution and the resulting precipitate was filtered off and washed with MeOH . Beige powder ( $0.06 \mathrm{~g}, 53 \%$ ). $\mathrm{C}_{8} \mathrm{H}_{6} \mathrm{CoN}_{5} \mathrm{O}_{2}$ : calcd. C 36.52 , H 2.30 , N $26.62 \%$; found C 36.96 , H 2.64, N 26.27\%. IR (KBr): v = 3124, 2069, 1649, 1612, 1547, 1475, 1462, 1361, 1302, $1249,1164,1111,1009,913,901,809,793,751,727 \mathrm{~cm}^{-1}$. Magnetic moment: 4.92 B.M.

### 3.5.4.2.14 $\left[\mathrm{Co}(3.1 \text { pytza })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]_{2}(3.23)$

3.1 ( $0.10 \mathrm{~g}, 0.43 \mathrm{mmol}$ ) was suspended in deionised $\mathrm{H}_{2} \mathrm{O}(15 \mathrm{~mL})$ and $\mathrm{NaOH}(0.01 \mathrm{~g}, 0.43$ mmol ) in deionised $\mathrm{H}_{2} \mathrm{O}$ was added to this solution and the resulting mixture was heated to reflux for 1 h . An aqueous solution of $\mathrm{Co}(\mathrm{SCN})_{2}$ in was added to the solution and the resulting pink solution was allowed to stand at room temperature for several days. The orange solid formed was filtered and washed with $\mathrm{H}_{2} \mathrm{O}$. Orange solid ( $0.03 \mathrm{~g}, 29 \%$ ). $\mathrm{C}_{16} \mathrm{H}_{14} \mathrm{CoN}_{10} \mathrm{O}_{5}$ : calcd. C 39.58 , H 2.91 , N $28.87 \%$; found C 38.97 , H 2.49 , N $27.93 \%$. IR (KBr): $v=3124,1650,1611,1547,1475,1462,1433,1360,1301,1247,1164,1111,1008$, $913,800,793,751,727 \mathrm{~cm}^{-1}$. Magnetic moment: 5.17 B.M.

### 3.5.4.2.15 $\left[\operatorname{Co}(3.2 p y t z a)\left(\mathrm{H}_{2} \mathrm{O}\right)(\mathrm{SCN})\right]_{\mathrm{n}}(3.24 \mathrm{a})$ and $\left[\mathrm{Co}(3.2 \text { pytza) }(\mathrm{SCN})]_{\mathrm{n}}\right.$ (3.24b)

$3.2(0.10 \mathrm{~g}, 0.43 \mathrm{mmol})$ was dissolved in $\mathrm{H}_{2} \mathrm{O} . \mathrm{NaOH}(0.01 \mathrm{~g}, 0.43 \mathrm{mmol})$ in deionised $\mathrm{H}_{2} \mathrm{O}$ was added to the solution and this was heated to reflux for $1 \mathrm{~h} . \operatorname{Co}(\mathrm{SCN})_{2}(0.08 \mathrm{~g}, 0.43$ mmol ) in MeOH was added to the mixture. A pink precipitate formed which was filtered off and washed with MeOH to yield $\mathbf{3 . 2 4 a}$. Pink powder ( $0.13 \mathrm{~g}, 85 \%$ ). $\mathrm{C}_{9} \mathrm{H}_{10} \mathrm{CoN}_{6} \mathrm{O}_{4} \mathrm{~S}$ : calcd. Data correlates well with literature data. ${ }^{173}$

## Chapter 4: Dicarboxylate Functionalised Pyridyl Tetrazoles

### 4.1 Introduction

As previously discussed in Chapter 1 and Chapter 3, the design and synthesis of coordination polymers (CPs) has received considerable attention over the last number of years. This is due to their potential applications in a number of areas including gas storage, sensors and drug delivery. The general synthetic strategy for designing such materials involves using multidentate ligands containing 0 - or N -donor groups. Examples of such ligands include polycarboxylic acids and bipyridines. Due to their diverse coordination modes and sensitivity to pH values, symmetrical rigid aromatic 0 -donor ligands such as phthalic acid and terephthalic acid (Figure 4.1), have been extensively studied. Many multidimensional polymers possessing interesting properties incorporating these type of ligands have been reported ${ }^{151}$ and a number have been utilised in combination with N donor ligands to synthesise mixed linker containing CPs. ${ }^{190}$

Figure 4.1: Phthalic acid (left) and terephthalic acid (right) are commonly used ligands in coordination polymers due to their high symmetry and diverse coordination modes.

In contrast, asymmetrical and flexible carboxylic acids have rarely been used, and the study on structures constructed from these type of ligands remains undeveloped. The lack of documented examples of multi-carboxylate ligands with rigid and flexible carboxylate groups may be attributed to the unpredictable structure types and also due to their unfavourable crystallisation conditions. ${ }^{191}$ Furthermore, examples of asymmetric carboxylates in combination with asymmetric N -donor spacers are extremely limited. The majority of examples report the use of N -donor ligands as ancillary ligands, and these are often symmetrical ligands such as $4,4^{\prime}$-bipyridine. ${ }^{191,192} \mathrm{~N}$-donors can modify the structures and properties of the resulting materials by the cooperative coordination with carboxylate groups to meet the requirement of coordination geometries of metal ions in the assembly process. ${ }^{191}$

### 4.1.1 Asymmetric Carboxylates as Linkers in CPs

The most common asymmetrical carboxylate ligand utilised in the construction of CPs is homophthalic acid (Figure 4.2). Compared to symmetrical ligands like phthalic acid and terephthalic acid, homophthalic acid has a relatively flexible ethylic carboxyl group which may not be co-planar with the benzene ring in the molecule. This flexibility endows the ligand with the capacity to adopt various conformations as well as coordination modes. ${ }^{193}$

Figure 4.2: Homophthalic acid.

In one example, Wang and co-workers employed homophthalic acid as a ligand along with an N -donor auxiliary ligand, (1,4-bis(imidazol-1-yl-methyl)benzene), to construct MOFs employing solvothermal methods. ${ }^{192}$ The resulting networks exhibited diverse structures and coordination modes at the metal ions. It was noted that the nature of the metal ion and its coordination geometry led to variation in the structures obtained, as the synthetic conditions were almost the same. For instance, in complexes 4.1 and 4.2 the $\mathrm{Zn}(\mathrm{II})$ is in a tetrahedral geometry with $\mathrm{N}_{2} \mathrm{O}_{2}$ donor set, while the Cd(II) has an octahedral geometry with $\mathrm{O}_{5} \mathrm{~N}_{1}$ donor set (Figure 4.3). The diversity of the final structures was also attributed to the different conformations adopted by the N -donor ligand and in particular the 0 donor ligand whose diverse coordination modes and flexibility allowed adjustments to occur during the assembly process. Several other authors have similarly utilised homophthalic acid in combination with other N -donor auxiliary ligands and have achieved interesting diverse structures. ${ }^{191,194}$ Despite the success in employing this ligand as an asymmetric linker, it is apparent that work on this ligand has been documented to the point of exhaustion and there is a distinct paucity of examples utilising other asymmetric linkers. Hence, this is an area that is worth exploiting further and is likely to yield interesting results.

### 4.2 Aims and Objectives of Chapter

Taking the considerations mentioned previously into account, we focused our attention on the construction of CPs based on asymmetric carboxylate ligands. Further developing the linkers used in Chapter 3 ( $\mathbf{3 . 1}$ (pytza) and $\mathbf{3 . 2}$ (pytza), Figure 4.4), the addition of a carboxylic acid group tethered to the pyridyl unit was proposed (Figure 4.4). 3.1(pytza) and 3.2 (pytza) possessed the donor capabilities of carboxylate oxygens and pyridyl tetrazole nitrogens. Addition of another carboxylate on the pyridine ring would endow the linker with more coordinative possibilities and could be more conducive to forming higher dimensional infinite arrays. $\mathbf{3 . 1}$ (pytza) and $\mathbf{3 . 2}$ (pytza) possessed an alkyl carboxylic acid positioned on the tetrazole ring. In the formation of the CPs, it was observed that this group could orientate itself in a number of ways and in most cases, it was not co-planar with the tetrazole ring. In the case of $\mathbf{4 . 3}$ (pytzda) and $\mathbf{4 . 4}$ (pytzda), it was anticipated that the combination of an alkyl carboxylate with the co-planar aromatic carboxylate would lead to higher dimensionality and diversity in the frameworks. Considering the breadth of multifunctional linkers, some of which are discussed in Chapter 3, multifunctional linkers with both rigid and flexible carboxylic acid groups are severely under-investigated. Hence, we aimed to further develop the range of asymmetric carboxylate linkers while at the same time incorporating asymmetric N -donors into the linker. To the best of our knowledge, there are no reports in the literature that employ a linker using both asymmetric nitrogen donors and mixed carboxylate groups. Thus, this report is the first to explicitly describe this approach in the synthesis of CPs.

3.1(pytza)

4.3(pytzda)

3.2(pytza)

4.4(pytzda)

Figure 4.4: Structures of the first generation linkers synthesised in Chapter 3 and the second generation linkers that were intended to be synthesised and employed in the synthesis of CPs.

In previous chapters, synthesis of linkers began with a 1,3-dipolar cycloaddition between 2 -cyanopyridine and sodium azide. However, this relied on the nitrile being commercially available. In this case, an appropriate nitrile was not commercially available. Thus, an objective of this work was to develop a strategy to synthesise 4.3 and 4.4. As before, the ester derivatives would need to be synthesised first in order to aid in the separation of the regioisomers (Figure 4.5). We aimed to carry out the hydrolysis of the esters in situ in order to generate $\mathbf{4 . 3}$ (pytzda) and $\mathbf{4 . 4 ( p y t z d a ) ~ ( F i g u r e ~ 4 . 4 ) ~ w h i c h ~ w o u l d ~ t h e n ~ b e ~}$ available to react with metal salts. As discussed in section 2.3.1, two regioisomers were expected in the formation of 4.3 and 4.4, thus allowing an investigation into regiochemical effects on the structures of CPs.

4.3

4.4

Figure 4.5: Synthesis of ester derivatives $\mathbf{4 . 3}$ and $\mathbf{4 . 4}$ was intended prior to the synthesis
of CPs.

Finally, CPs are of significant interest due to their physical properties, ${ }^{181}$ hence we aimed to examine the luminescent properties of the resulting Zn (II) structures and to carry out EPR studies on $\mathrm{Cu}(\mathrm{II})$ structures.

Ultimately, our aims were to synthesis 4.3 and 4.4; to utilise these ligands to construct metal organic complexes with interesting topologies and properties for potential application; to investigate the factors influencing the coordination mode of the ligands and the final structure of the complexes and to investigate the physical properties of the resulting materials.

### 4.3 Results and Discussion

### 4.3.1 Synthesis of Diester Pyridyl Tetrazoles 4.3 and 4.4

### 4.3.1.1 Synthetic Approach

The synthetic strategy developed in order to gain access to the diester derivatives 4.3 and 4.4 involved consideration of pyridine ring reactivities. In order to install a tetrazole moiety in the 2-position of the pyridine, the presence of a nitrile was required in this position. The timing of the instalment of a carboxylic acid moiety in the 4-position also had to be considered. Synthesis could have commenced from either 2-cyanopyridine or isonicotinic acid, however, on examining the potential routes starting from both precursors, a route involving nucleophilic substitution of isonicotinic acid was chosen. This was due to a number of reasons. Firstly, pyridine rings can only undergo electrophilic substitution if they are activated by electron-donating substituents. ${ }^{123}$ Nitrile groups and carboxylic acid groups are both electron withdrawing substituents, thus, electrophilic substitution using either of the above starting materials would have proved a difficult task. On the other hand, carrying out nucleophilic substitution on either starting material could have been possible. The most efficient way of carrying out nucleophilic substitution on a pyridine ring is to oxidise the pyridine nitrogen to yield an N-oxide. ${ }^{123}$ The N-O moiety of pyridine N -oxides possess a unique functionality which can act effectively as a push electron donor and as a pull electron acceptor group by virtue of the resonance forms shown in Scheme 4.1. ${ }^{195}$

Scheme 4.1: Resonance forms of pyridine-N-oxide.

Secondly, on examination of the literature, nucleophilic substitution on 2-cyanopyridine resulted in low yields and a mixture of products. ${ }^{196}$ Thus, nucleophilic substitution starting from isonicotinic acid was considered the best approach, as nitrile attack would only occur at the 2 -position due to the carboxylic acid function being present at the 4 -position. This group would effectively protect this position.

The nucleophilic substitution of the oxidised pyridine ring was then considered. Classic $\alpha$ cyanation of pyridine N -oxides is achieved via a Reissert-Henze reaction using benzoyl chloride and a cyanide ion. ${ }^{197}$ Modifications to this reaction has involved the use of trimethylsilanecarbonitrile (TMSCN) in the presence of different acylating agents. ${ }^{198,199}$ In 2008, Huo and colleagues developed a zinc cyanide $\left(\mathrm{Zn}(\mathrm{CN})_{2}\right)$ mediated direct $\alpha$-cyanation of isonicotinic acid N -oxide with the objective of avoiding the use of expensive TMSCN. ${ }^{200}$ An acylating agent, dimethylcarbamoyl chloride (DMCC), was also used in the reaction and the proposed reaction mechanism is shown in Scheme 4.2. At the initial stage of the reaction, the 1 -acyloxypyridinium intermediate ion 4.5 is formed as mentioned in previous reports in the literature. ${ }^{198,201}$ The $\alpha$-cyanation reaction of this intermediate with $\mathrm{Zn}(\mathrm{CN})_{2}$ and elimination of carbon dioxide affords the tetrahedral intermediate 4.6. Removal of $\mathrm{N}, \mathrm{N}$-dimethylcarbamic acid from 4.6 then gives 2 -cyanoisonicotinamide (4.7).

Scheme 4.2: The mechanism proposed by Huo et al. for the formation of an $\alpha$-cyanated pyridine. ${ }^{200}$

We further modified these reaction conditions to suit our purposes and our proposed synthetic route can be seen in Scheme 4.3. Firstly, protection of the carboxylic acid moiety
would be carried out to avoid formation of the N -carbamoyl group, followed by oxidation of the pyridine nitrogen to form the N -oxide (4.9a/4.9b). Cyanation of the 2-position would be carried out under similar conditions employed by Huo and co-workers to obtain 4.10a/4.10b. Subsequent 1,3-dipolar cycloaddition and alkylation of the tetrazole ring would yield ligands 4.3 and 4.4 (Scheme 4.3).

Scheme 4.3: Intended synthetic route to obtain the diester derivatives $\mathbf{4 . 3 a / b}$ and $\mathbf{4 . 4 a} \mathbf{b}$.

### 4.3.1.2 Synthesis of Ligands 4.3 and 4.4

Synthesis commenced with esterification of isonicotinic acid to the methyl ester employing typical esterification conditions. ${ }^{123,202,203}$ Characterisation data obtained for the yellow oil (4.8a) was in agreement with literature data, ${ }^{202}$ with a singlet observed in the ${ }^{1} \mathrm{H}$ NMR spectrum at 3.96 ppm integrating for 3 protons, and a ${ }^{13} \mathrm{C}$ NMR resonance at 52.6 ppm being the main indication of the presence of a methyl ester functionality. In order to activate the 2-position towards nucleophilic attack, oxidation of the pyridine ring was required. Oxidation of heterocycles can be obtained in good yields using peracetic acid. This is a strong oxidant that has uses in disinfection, bleaching of textiles and pulps and in the epoxidation of olefins. ${ }^{204}$ Generally, peracetic acid can be prepared in two ways; from hydrogen peroxide or by oxidation of acetaldehyde. For the purpose of this project, the acetic acid-hydrogen peroxide method was used. Sulfuric acid can be used as a strong acid
catalyst to accelerate the rate of equilibrium of this reversible reaction, however its use was not required in our case. The process is described by the following scheme:

Scheme 4.4: Formation of peracetic acid from acetic acid and hydrogen peroxide.

The mechanisms of peracetic acid synthesis have been studied previously. ${ }^{204,205}$ Using an ${ }^{18} \mathrm{O}$ isotope label, it was found that the reaction did not involve dissociation of the $0-0$ bond in hydrogen peroxide. 204 The hydrolysis of peroxy acids synthesised from $\mathrm{HC}^{18} \mathrm{OOH}$ or $\mathrm{CH}_{3} \mathrm{C}^{18} \mathrm{OOH}$ afforded hydrogen peroxide containing no radiolabelled oxygen $\left({ }^{18} \mathrm{O}\right)$. This evidence indicated that the bond between the acyl group and oxygen atom was cleaved in both the formation and hydrolysis of peroxy acids. ${ }^{204}$ Rubio et al. studied the mechanism of formation of peracids taking the reaction between formic acid and hydrogen peroxide as a model for the generation of performic acid. ${ }^{205}$ They proposed two routes for the formation of performic acid (Scheme 4.5). Route A consists of the addition of the hydrogen peroxide to the carbonyl carbon to form a tetrahedral transition state with the subsequent loss of a $\mathrm{H}_{2} \mathrm{O}$ molecule; Route B is carried out in an acidic medium for the activation of the carbonyl carbon with subsequent addition of the hydrogen peroxide and the loss of a $\mathrm{H}_{2} \mathrm{O}$ molecule. ${ }^{205}$ Route B is proposed to be the preferred pathway, as the organic acid (in our case acetic acid) can provide a source of $\mathrm{H}^{+}$when there is no acid catalyst in the reaction system, thereby accelerating the reaction.

## Route A

## Route B

Scheme 4.5: Two proposed routes by which peracetic acid can form, as proposed by Rubio et al. ${ }^{205}$ Route A involves attack of hydrogen peroxide on the carbonyl carbon of the acid with subsequent loss of $\mathrm{H}_{2} \mathrm{O}$. Route B involves an acid catalysed mechanism with hydrogen peroxide addition and loss of $\mathrm{H}_{2} \mathrm{O}$.

Oxidation of the pyridine ring is achieved by nucleophilic attack from the nitrogen on the peracetic acid oxygen followed by subsequent deprotonation. Oxidation of 4.8a was achieved in this way and after treatment with base and extraction with ethyl acetate a pale yellow solid was afforded. Confirmation that the pale yellow solid was indeed the N -oxide 4.9a was attained through characterisation by NMR and IR spectroscopies which was consistent with the data obtained in literature reports. ${ }^{206,207}$ The IR spectrum was notably different from the unoxidised pyridine ring 4.8a with the presence of a $v(\mathrm{~N}-\mathrm{O})$ stretching frequency at $1262 \mathrm{~cm}^{-1}$. A cyanation reaction was then carried out utilising a modified method of that carried out by Huo et al. ${ }^{200}$ The reaction was carried out in toluene, using conventional heating methods employing DMCC as the acylating agent and $\mathrm{Zn}(\mathrm{CN})_{2}$ as the cyanide source. Substitution of the symmetrical N -oxide 4.9 a in the 2-position would result in an additional peak resonating in the ${ }^{1} \mathrm{H}$ NMR spectrum as symmetry in the molecule would be lost. On analysis of the pale orange product 4.10a, the successful substitution of a nitrile group at the 2 -position was indicated, as three aromatic resonances were observed at $8.07,8.24$ and 8.07 ppm in the ${ }^{1} \mathrm{H}$ NMR spectrum. The ${ }^{13} \mathrm{C}$ NMR spectrum also displayed three extra signals compared to the spectrum of 4.9a due to this loss of symmetry, creating eight inequivalent carbon environments. The nitrile ${ }^{13} \mathrm{C}$ signal was observed at 115.5 ppm . The IR spectrum also confirmed the presence of a nitrile group as a $v(\mathrm{C} \equiv \mathrm{N})$ frequency was positioned at $2237 \mathrm{~cm}^{-1}$. The obtained data for 4.9a was also consistent with a literature report, ${ }^{208}$ indicating that our modified $\alpha$ -
cyanation of a pyridine ring was successful. This method afforded comparable yields to those in literature reports ( $\sim 65 \%$ ) and offers a safer methodology as cheap $\mathrm{Zn}(\mathrm{CN})_{2}$ is employed which is relatively less toxic than TMSCN, NaCN and KCN. A 1,3-dipolar cycloaddition was then carried out using conditions utilised previously (section 2.3.1). On recovery of the protonated 5 -substituted tetrazole 4.11a, issues were encountered in the acidic work-up. Yields were poor, and often following an extraction, the hydrolysed product was encountered. Although this result was not a considerable diversion from our intended synthetic route, there was concern over the feasibility of purifying regioisomers if a carboxylic acid was present. In addition, the low yields of the methyl ester derivative would have made the synthesis of the coordination polymers an inefficient and time consuming task. Thus, a simple solution was proposed. Taking into consideration the reactivity of a methyl ester towards ester hydrolysis in aqueous acidic conditions, it was anticipated that a less reactive ester would be more stable in these conditions, therefore allowing isolation of the 5-substituted tetrazole with the ester functionality intact. Conversion of the carboxylic acid to a less reactive ethyl ester did indeed alleviate these problems and isolation of $\mathbf{4 . 1 1 b}$ was achieved consistently with yields $>70 \%$ after recrystallisation in EtOH. Presence of the tetrazole ring was alluded to as another aromatic ${ }^{13} \mathrm{C}$ signal was present in the ${ }^{13} \mathrm{C}$ NMR spectrum accompanied by the concomitant disappearance of the nitrile ${ }^{13} \mathrm{C}$ peak. Consumption of the nitrile was also indicated by the disappearance of a $v(C \equiv N)$ frequency in the IR spectrum of $4.11 b$. Presence of a broad stretch positioned at $3083 \mathrm{~cm}^{-1}$ was attributed to a $v(\mathrm{~N}-\mathrm{H})$ frequency, which further pointed towards the presence of a protonated tetrazole ring. This broad stretch was not considered to be a carboxylic acid OH stretch as the presence of ethoxy protons at 1.38 and 4.43 ppm in the ${ }^{1} \mathrm{H}$ NMR spectrum indicated that the ester group remained intact. Finally, analysis by HRMS confirmed the successful synthesis of 4.11b. Alkylation of 4.11b using ethyl bromoacetate in the presence of $\mathrm{K}_{2} \mathrm{CO}_{3}$ yielded two regioisomers, 4.3 and 4.4. Analysis of the crude mixture of 4.3 and 4.4 by ${ }^{1} \mathrm{H}$ NMR spectroscopy revealed a ratio of $\sim 10: 12$ of $\mathrm{N}-1$ to $\mathrm{N}-2$ isomers being produced, which represents a distinct lack of regioselectivity. However, in comparison to the ester derivatives $\mathbf{3 . 1}$ and $\mathbf{3 . 2}$ which were discussed in Chapter 3, which showed similar regioselectivity, this result was to be expected. The two isomers were purified by flash column chromatography and identification and assignment of the position of the alkylated site was possible by analysis of the products by ${ }^{13} \mathrm{C}$ NMR spectroscopy. The C-5 of the tetrazole ring resonated at 151.8 ppm for the $\mathrm{N}-1$ substituted isomer and 164.7 ppm for the $\mathrm{N}-2$ substituted isomer. The protons of the methylene group were again more downfield for the $\mathrm{N}-1$ isomers than for the $\mathrm{N}-2$ isomers due to the anisotropic effects of the pyridine ring (Figure 4.6). The
presence of the alkyl ester functionality was also confirmed by the presence of another carbonyl ${ }^{13} \mathrm{C}$ peak at $\sim 165 \mathrm{ppm}$ and another $v(\mathrm{C}=0)$ frequency visible at $\sim 1725 \mathrm{~cm}^{-1}$.

### 4.3.2 Metal Complexation Reactions

### 4.3.2.1 Metal Complexation Reactions with Diester Derivatives 4.3 and 4.4

Coordination studies were carried out with 4.3 and 4.4 as it was thought that they could offer interesting coordination chemistry in their own right. One equivalent of metal salt relative to the ligands were employed.

Addition of $\mathrm{CuCl}_{2} 2 \mathrm{H}_{2} \mathrm{O}$ to a solution of 4.3 in MeOH resulted in a vibrant green solution. After heating the solution to reflux for 2 h , the solution was allowed to sit at room temperature for several days. The resulting green solids (4.12) were isolated and characterised. IR analysis on the solid 4.12, indicated that complexation to the ester moiety was not occurring as there was not a significant shift in the $v(\mathrm{C}=0)$ frequencies. Slight shifts of $\sim 10 \mathrm{~cm}^{-1}$ were observed however, suggesting that the ligand had complexed to the $\mathrm{Cu}(\mathrm{II})$ ion. Shifts were observed for the heterocyclic frequencies, with $v(\mathrm{C}=\mathrm{N})_{\text {pyr }}, v(\mathrm{C}=\mathrm{N})_{\text {tet }}$ and $v(\mathrm{~N}=\mathrm{N})$ frequencies shifting from 1604, 1537 and $1433 \mathrm{~cm}^{-1}$ to 1618,1560 and $1458 \mathrm{~cm}^{-1}$ respectively. Elemental analysis suggested that the solid had a 1:1 metal to ligand composition, and the presence of four chloride anions correlated well with these results. Hence, it was proposed that the complex consisted of a dichlorobridged species, with each $\mathrm{Cu}(\mathrm{II})$ centre in a square pyramidal geometry (Figure 4.7).

Figure 4.7: Proposed structure of 4.12.

Figure 4.8: Crystal structure of 4.12.

Crystals suitable for single crystal X-ray diffraction were obtained and the results obtained established that 4.12 was indeed made up of a dichloro-bridged structure (Figure 4.8) and that each $\mathrm{Cu}(\mathrm{II})$ ion was coordinated to three chloride anions (two of which were $\mu$ - Cl bridging chlorines), a pyridine nitrogen and a tetrazole nitrogen. The dimeric complex lies on a crystallographic inversion centre which lies at the centre of the $[\mathrm{Cu}(\mathrm{II})(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}$ core and this structure is similar to the previously discussed copper dimer complexes in Chapter 2 (Figure 2.11) and Chapter 3 (Figure 3.13). The $\mathrm{Cu}(\mathrm{II})$ ion is in a distorted square pyramidal geometry, with a very long Cu1 $\cdots \mathrm{Cl} 2$ bond compared to other coordinative bonds ( $2.76 \AA$ compared to $2.10-2.25 \AA$ for all other bonds). According to Halcrow, only Cu-L interactions up to $2.4 \AA$ should be considered as genuine Cu-L bonds, with longer bonds representing weaker, secondary interactions. ${ }^{55}$ Therefore, on examination of the bond lengths in 4.12, it could be implied that the complex is more square-planar in geometry. Each pyridyl tetrazole ligand binds to the $\mathrm{Cu}(\mathrm{II})$ atom through one tetrazole N atom at the $\mathrm{N}-1$ site of the tetrazole ring and through the pyridyl N atom, generating a fivemembered chelate ring. The 5 -membered tetrazole ring is slightly twisted with respect to the 6 -membered pyridyl ring at an angle of $11.1(3)^{\circ}$.

Addition of $\mathrm{CuCl}_{2} 2 \mathrm{H}_{2} \mathrm{O}$ to a methanolic solution of 4.4 resulted in an emerald green solution. After heating to reflux for 2 h the solution was allowed to stand at room temperature for several days. The resulting mint green solid, 4.13, was filtered and dried. IR spectral analysis of the solid revealed that the two $v(\mathrm{C}=0)$ vibrational modes had a smaller difference in frequency than the starting material. Shifts in the heterocyclic frequencies were also observed. Elemental analysis indicated a 1:2 metal to ligand composition. Elemental analysis also suggested that the ethyl groups were no longer present. This could be explained by the process of transesterification. Transesterification is the process of exchanging an ester R group to a different R group of an alcohol. ${ }^{123}$ This process was plausible in this case, as MeOH was employed as the reaction solvent and was therefore in excess. This would result in the methyl ester derivative being produced, which would explain the observed elemental analysis results. Therefore, a structure was proposed which is shown in Figure 4.9. This octahedral complex is similar to the complex 3.9 that was discussed in section 3.3.2.1.

Figure 4.9: Proposed structure of 4.13.

Reaction of $\operatorname{Co}(\mathrm{SCN})_{2}$ with 4.4 resulted in a pink solution which turned blue on standing at room temperature for several days. An orange/pink crystalline solid, 4.14, formed which was filtered off, washed with MeOH and dried. The IR spectrum of 4.14 revealed that there was no interaction between the metal ion and the ester moiety, as shifts of $\sim 50 \mathrm{~cm}^{-1}$ were not observed for the $v(\mathrm{C}=0)$ frequencies, although smaller shifts were visible. Shifts in the heterocyclic ring frequencies were evident with bands shifting from 1605, 1564, 1427 $\mathrm{cm}^{-1}$ to 1622,1570 and $1432 \mathrm{~cm}^{-1}$. Presence of thiocyanate anions were also revealed, with very strong $v(\mathrm{C}=\mathrm{N})_{\text {scs }}$ frequencies positioned at 2093 and $2081 \mathrm{~cm}^{-1}$. These values are above what classically N -bonded thiocyanato anions would vibrate at, however they
are consistent with obtained experimental values reported in the literature. ${ }^{150}$ Elemental analysis of 4.14 indicated a $1: 2$ metal to ligand composition. Elemental analysis also suggested that transesterification had occurred. Taking into consideration the obtained data for 4.14, a structure was proposed and can be seen in Figure 4.10. The complex consists of an octahedral Co(II) centre, coordinated by two pyridyl tetrazole ligands in the equatorial plane and two isothiocyanate anions in the axial positions.

Figure 4.10: Proposed structure of 4.14.

A crystal was grown of complex 4.14 and was analysed by single crystal X-ray crystallography (Figure 4.11). The results established a distorted octahedral environment around the $\mathrm{Co}(\mathrm{II})$ centre and confirmed that transesterification had occurred. The orientations of the ligands, however, are different to what was observed in previous $\mathrm{Co}(\mathrm{SCN})_{2}$ complexes synthesised in this work. Instead of the two pyridyl tetrazole ligands occupying the equatorial planes of the octahedron as had previously been observed, one ligand now occupies the axial position and the other occupies the equatorial position. This is also the case for the thiocyanate anions, which are cis to each other. The structure shares similarities with the comprehensively studied $\left[\mathrm{Ru}(\text { bipy }-\mathrm{R})_{2}(\mathrm{NCS})_{2}\right]$ series of complexes. 209

Figure 4.11: Crystal structure of 4.14 .

Comparing these reactions to those carried out with the mono-ester derivatives in Chapter 3, it was again evident that the position of the alkylated site of the tetrazole ring was influencing the geometry that the metal centre was adopting. With the prospect of using the carboxylate derivatives of 4.3 and 4.4 in CP synthesis, these regiochemical effects promised interesting results.

### 4.3.2.2 In situ Hydrolysis and Metal Complexation Reactions with 4.3(pytzda) and 4.4(pytzda)

4.3 and 4.4 were converted to their respective carboxylates in situ by nonsolvothermally heating aqueous NaOH solutions of the ligands (Scheme 4.6). After two hours, aqueous solutions of metal salts (one equivalent) were added to the solutions. These solutions were then cooled slowly and allowed to stand at room temperature for several days or in some cases weeks. On slow evaporation of the mother liquor, crystalline solids were obtained and in some instances, crystals formed that were suitable for single crystal X-ray crystallography. Each product was analysed by IR spectroscopy, elemental analysis and magnetic moment measurements. In the case of the Cu (II) products, EPR spectroscopy was also performed. For the Zn (II) products, NMR spectroscopy was also undertaken. One Zn (II) complex, 4.21 was subjected to solid state fluorescence studies.

Scheme 4.6: Reagents and conditions: (i) $\mathrm{NaOH}, \mathrm{H}_{2} \mathrm{O}, \Delta, 2 \mathrm{~h}$.

### 4.3.2.2.1 Coordination polymer formation employing 4.3(pytzda)

A blue crystalline solid was obtained in the reaction of 4.3 (pytzda) with $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}$. IR spectral analysis of the solid 4.15 indicated that no protonated carboxylic acid was present as the peak associated with this vibrational mode was absent ( $\sim 1726 \mathrm{~cm}^{-1}$ ). Antisymmetric carboxylate vibrations ( $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$) were positioned at $1619 \mathrm{~cm}^{-1}$ and 1555 $\mathrm{cm}^{-1}$. Corresponding symmetric vibrations ( $\mathrm{v}_{\text {sym }}\left(\mathrm{COO}^{-}\right)$) were positioned at 1392 and $1365 \mathrm{~cm}^{-1}$. These observations suggested that there were two modes of coordination that the carboxylates were adopting. Also visible in the IR spectrum of 4.15 was a very broad stretch in the range of $2966-3577 \mathrm{~cm}^{-1}$ which was centred at $3230 \mathrm{~cm}^{-1}$. This indicated the presence of $\mathrm{H}_{2} \mathrm{O}$ molecules coordinating to the metal ion and also that extensive hydrogen bonding was present in the structure. Elemental analysis of $\mathbf{4 . 1 5}$ suggested a 1:1 ratio of metal to ligand. The single blue crystals that were obtained in this reaction were analysed by X-ray crystallography, the results of which can be seen in Figure 4.12. The asymmetric unit of $\mathbf{4 . 1 5}$ consists of a dinuclear structure, with one $\mathrm{Cu}(\mathrm{II})$ ion coordinated by two $\mathrm{H}_{2} \mathrm{O}$ molecules, a tetrazole nitrogen and a pyridyl nitrogen, and the second $\mathrm{Cu}(\mathrm{II})$ centre coordinated by a carboxylate oxygen binding in a monodentate fashion and two $\mathrm{H}_{2} \mathrm{O}$ molecules. The Cu1 metal centre displays typical Jahn-Teller axial elongation in its distorted octahedral geometry (Cu1-01W $2.42 \AA$ Å, Cu1-N12 $2.04 \AA, \mathrm{Cu} 1-\mathrm{N} 21.99 \AA$ ). The Cu 2 metal centre is also in a distorted octahedral geometry, however the distortions are not quite as pronounced compared to the Cu1 atom. This bonding arrangement generates a 1-D CP (Figure 4.13) that has a wavelike topology. The waves result from a 'kink' created
by the coordination geometry around the Cu 2 centre. Extensive hydrogen bonding is present throughout the structure by virtue of the $\mathrm{H}_{2} \mathrm{O}$ molecules (Figure 4.13). The coordinating $\mathrm{H}_{2} \mathrm{O}$ molecules on Cu 1 act as both hydrogen bond donors (to carboxylate oxygens) and acceptors (to the $\mathrm{H}_{2} \mathrm{O}$ of crystallisation). The coordinating $\mathrm{H}_{2} \mathrm{O}$ molecules on Cu 2 act solely as hydrogen bond donors to carboxylate oxygens from other polymeric chains.

Figure 4.12: (a) Subunit of 4.15. The Cu2 metal centre gives rise to the 'kink' in the coordination polymer. (b) View along the $c$-axis of 4.15. (c) Packing diagram viewed along the $b$-axis with hydrogen bonding connecting the polymers visible.

Reaction of 4.3 (pytzda) with $\mathrm{NiCl}_{2}$ yielded blue crystals (4.16) on slow evaporation of the mother liquor. On IR analysis of the crystals, it became clear that there were several similarities between the IR spectrum of 4.16 and that of 4.15. Firstly, $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$ vibrations were observed at $\sim 1622$ and $1553 \mathrm{~cm}^{-1}$ with two corresponding $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$ vibrations at 1389 and $1364 \mathrm{~cm}^{-1}$ (Figure 4.13), indicating that there were two different types of carboxylate coordination existing in the structure. These were most likely ionic or monodentate in nature as bidentate or bridging carboxylates would have yielded much smaller $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$values than those observed in this instance $(\Delta=233$ and $\left.189 \mathrm{~cm}^{-1}\right) .{ }^{150} \mathrm{~A}$ broad peak in the range $3189-2563 \mathrm{~cm}^{-1}$ was also observed, which was attributed to hydrogen bonded $0-H$ groups. Elemental analysis indicated a $1: 1$ metal to ligand composition. The crystal structure obtained for $\mathbf{4 . 1 6}$ was consistent with the data obtained and the X-ray structure can be seen in Figure 4.14. The structure was
isomorphic to the $\mathrm{Cu}(\mathrm{II})$ coordination polymer 4.15, apart from the lack of Jahn-Teller distortions observed, which was expected for an octahedral $\mathrm{d}^{8}$ metal centre. The packing diagram of $\mathbf{4 . 1 6}$ (Figure 4.14) displays these wavelike polymers propagating diagonally.

Figure 4.13: IR spectrum of 4.16.
(a)

(b)

Figure 4.14: (a) Subunit of the coordination polymer 4.16. (b) View along the $b$-axis of packing diagram of 4.16.

Reaction of 4.3 (pytzda) with $\operatorname{Co}(S C N)_{2}$ yielded block-like orange crystals (4.17) on evaporation of the mother liquor. These crystals were analysed by IR spectroscopy and again the spectrum showed remarkable similarities to those of 4.15 and 4.16. $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$ vibrations were positioned at 1621 and $1553 \mathrm{~cm}^{-1}$ and $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$vibrations were positioned at 1386 and $1362 \mathrm{~cm}^{-1}$. This indicated that there were mixed carboxylate groups present and that they were adopting two modes of coordination. The IR spectrum also indicated the presence of hydrogen bonded $0-H$ bonds as a broad stretch centred at $3130 \mathrm{~cm}^{-1}$ was present. An absence of peaks at $\sim 2070 \mathrm{~cm}^{-1}$ confirmed that there were no thiocyanate anions present in the structure. Elemental analysis alluded to a 1:1 composition of metal to ligand and analysis of the crystals by X-ray crystallography confirmed this to be the case (Figure 4.15). In 4.17, both Co(II) centres are in a distorted octahedral geometry, however the distortions are not as pronounced as those observed in

### 4.15.

Figure 4.15: Subunit of coordination polymer 4.17.

Reaction of 4.3 (pytzda) with $\mathrm{ZnCl}_{2}$ yielded opaque white crystals (4.18) on slow evaporation of the mother liquor. Elemental analysis suggested a 1:1 metal to ligand composition and IR spectroscopy of the crystals indicated that there were two different modes of carboxylate coordination occurring as splitting of the $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$and $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$ vibrations were evident. It was also noted that the spectrum followed similar patterns observed in the IR spectra of previously discussed products 4.15-4.17. X-ray crystallography established that $\mathbf{4 . 1 8}$ was isomorphic in structure to the previously discussed CPs (Figure 4.16). The distorted octahedral Zn 1 metal centre is axially elongated with a Zn1-01W bond length of $2.23 \AA$. NMR spectroscopy was performed on the diamagnetic species and this data was in agreement with the crystal structure. As expected, four resonances were observed in the ${ }^{1} \mathrm{H}$ NMR spectrum, with three peaks in the aromatic region arising from the pyridyl protons and a singlet at 5.56 ppm arising from
the methylene group bonded to the tetrazole ring. All of these resonances were observed to have shifted from the free acid, 4.3(pytzdaH), ${ }^{1} \mathrm{H}$ NMR resonances.

Figure 4.16: Subunit of the coordination polymer 4.18.

Therefore, a series of isomorphic CPs were synthesised and characterised. The attainment of isostructural complexes is not uncommon with several reports present in the literature. ${ }^{210,211}$ These results demonstrate that the coordination environment is determined essentially by the ligand, which is imposing its preferred geometry on the metal ion. This indicates that the ligand is minimising intramolecular ligand interactions through the enforcement of its preferred geometry. ${ }^{210}$

A fascinating structural feature of these CPs is the presence of free aromatic carboxylate chelation sites that are open to metal insertion. Addition of metals to uncoordinated metal sites in CPs is a successful method of post-synthetic modification (PSM). ${ }^{105}$ PSM, which was previously described in Chapter 1 (section 1.4.3), has attracted a lot of interest in recent years due to its success in imbuing the parent materials with modified chemical and physical properties. Attainment of CPs with free chelation sites that are available to bind to additional metal ions is difficult, as typically these sites predominantly are involved in the synthesis of the parent framework. For this reason, strategies have been reported in the literature where the CP is post-synthetically appended with a chelating group in order to metallate afterwards. The motivation behind this is to tailor the material towards certain applications like gas separation or absorption. First reported by Rosseinsky and colleagues, ${ }^{212}$ this concept has been used by a number of other groups in order to produce MOFs that could potentially be used for gas sorption and catalysis applications. ${ }^{213}$ However, this procedure requires a further synthetic step, which can compromise the structural integrity of the parent material. Hence, there are obvious advantages to directly synthesising a framework with free metal binding sites.

### 4.3.2.2.2 Reactions of 4.4 (pytzda)

4.4 was hydrolysed by nonsolvothermally heating it in aqueous NaOH solution. The in situ generated carboxylate was then reacted with various metal salts (one equivalent) and the resulting solutions were cooled and evaporated slowly over several days. The resulting crystalline solids were analysed by IR spectroscopy, elemental analysis and magnetic moment measurements and in some cases single crystals were obtained that were suitable for analysis by X-ray crystallography.

Reaction of 4.4 (pytzda) with $\mathrm{CuCl}_{2} 2 \mathrm{H}_{2} \mathrm{O}$ in $\mathrm{H}_{2} \mathrm{O}$ yielded a blue solution which when slowly reduced by slow evaporation yielded a blue crystalline solid (4.19). The IR spectrum of 4.19 indicated that no protonated carboxylate was present as there were no vibrational peaks observed at $\sim 1708$ and $1744 \mathrm{~cm}^{-1}$. The presence of carboxylates was indicated by the presence of $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$vibrations at 1623 and $1602 \mathrm{~cm}^{-1}$ and corresponding $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$vibrations at 1386 and $1423 \mathrm{~cm}^{-1}$. This gave $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-\right.$ $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$) values of 237 and $179 \mathrm{~cm}^{-1}$, which indicated both monodentate bound and ionic forms of carboxylate were present in the structure, as bidentate and bridging carboxylates would be expected to have much lower $\Delta$ values. ${ }^{150} \mathrm{~A}$ broad stretch was also observed at $3437 \mathrm{~cm}^{-1}$ which was attributed to $0-\mathrm{H}$ stretches from $\mathrm{H}_{2} \mathrm{O}$ molecules which appeared to be involved in hydrogen bonding. Elemental analysis suggested that the blue solid consisted of a $1: 1$ metal to ligand ratio. The proposed structure of $\mathbf{4 . 1 9}$ can be seen in Figure 4.17. It consists of a dinuclear complex, with each $\mathrm{Cu}(\mathrm{II})$ centre in an octahedral geometry. The octahedral geometry is fulfilled through coordination of a pyridine and tetrazole nitrogen, a carboxylate oxygen from a second ligand and three $\mathrm{H}_{2} \mathrm{O}$ molecules. This arrangement would give rise to the structure that is depicted in Figure 4.17.

Figure 4.17: Representation of the proposed structure of 4.19.

Reaction of 4.4 (pytzda) with $\mathrm{Co}(\mathrm{SCN})_{2}$ produced an orange crystalline solid when a dilute solution was allowed to evaporate slowly. An amorphous powder (4.20) was produced on
addition of the metal salt when more concentrated solutions were employed. The IR spectrum of 4.20 revealed the presence of carboxylates with a broad $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$vibration at $1619 \mathrm{~cm}^{-1}$ and $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$vibrations visible at 1398 and $1382 \mathrm{~cm}^{-1}$. A broad stretch at $3271 \mathrm{~cm}^{-1}$ was also observed indicating the presence of $\mathrm{H}_{2} \mathrm{O}$ molecules that were possibly involved in hydrogen bonding. Elemental analysis suggested a 1:1 metal to ligand composition and also indicated the presence of solvent molecules. The results of X-ray crystallographic analysis on the single crystals obtained in this reaction can be seen in Figure 4.18. 4.20 crystallises not as a coordination polymer but as an isolated dimeric complex. Each Co(II) centre possesses a distorted octahedral geometry and is coordinated to a pyridine and tetrazole nitrogen, a carboxylate oxygen from a second ligand coordinating in a monodentate manner and three $\mathrm{H}_{2} \mathrm{O}$ molecules. As was observed in the case of the $\mathrm{N}-1$ substituted coordination polymers, the aromatic pyridyl carboxylate does not take part in the coordination sphere of the metal ion.

Figure 4.18: X-ray crystal structure of dimer $\mathbf{4 . 2 0}$.

Reaction of 4.4 (pytzda) with $\mathrm{ZnCl}_{2}$ in $\mathrm{H}_{2} \mathrm{O}$ yielded clear block-like crystals (4.21) on slow evaporation of the mother liquor. The IR spectrum of the solid, 4.21, revealed that there was no protonated carboxylate present in the structure. A $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$vibration was observed at $1618 \mathrm{~cm}^{-1}$. However, this peak was broad and it was evident that there was a shoulder on this peak, which alluded to the presence of another $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$vibration. This opinion was further supported by the observation of two $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$vibrations at 1397 and $1381 \mathrm{~cm}^{-1}$. This pointed towards the presence of mixed carboxylates with different coordination modes. Considering the $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$values were $\sim 237 \mathrm{~cm}^{-1}$ it was proposed that the carboxylates were adopting both ionic and monodentate states. A broad stretch centred at $3406 \mathrm{~cm}^{-1}$ was also observed. This was proposed to arise from 0-

H vibrations from $\mathrm{H}_{2} \mathrm{O}$ molecules that were involved in hydrogen bonding. Elemental analysis of 4.21 suggested a 1:1 metal to ligand composition. Single crystals of 4.21 were obtained and were solved by X-ray crystallography. The results of this analysis can be seen in Figure 4.19.

Figure 4.19: Crystal structure of $\mathbf{4 . 2 1}$.
4.21 crystallises as an isolated dinuclear structure, with two equivalent $\mathrm{Zn}(\mathrm{II})$ centres and is isostructural with the $\mathrm{Co}(\mathrm{II})$ structure 4.20. The Zn (II) ion is in a distorted octahedral environment and is coordinated by one pyridyl tetrazole unit from one ligand via the pyridyl and tetrazole N -1 nitrogens; a carboxylate oxygen coordinating in a monodentate fashion from a second ligand; and three $\mathrm{H}_{2} \mathrm{O}$ molecules. There is a slight variation in the distance between the two metal centres however, with a distance of 7.24(1) $\AA$ present in 4.21 compared to 7.09 (4) $\AA$ in $\mathbf{4 . 2 0}$. Again, it was noted that the aromatic carboxylate was not partaking in the formation of 4.21. This led us to believe that the reactivities of the alkyl and aromatic esters were sufficiently different and that this difference could be exploited.

### 4.3.2.3 Preliminary Attempts at Complexing Aromatic Carboxylate

As discussed previously, the serendipitous attainment of complexes with free metal binding sites offers possibilities of fine-tuning the material for applications like selective adsorption or catalysis. Thus, some preliminary studies were carried out to determine whether coordination to the aromatic carboxylate could be achieved either in tandem with the alkyl carboxylate or post-synthetically.

The previously discussed reactions involved reacting one equivalent of metal salt with the ligands. Therefore, occupation of the alkyl carboxylate site was attempted by reacting 4.3 (pytzda) and 4.4 (pytzda) with two equivalents of metal salt $\left(\mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}, \mathrm{NiCl}_{2} .6 \mathrm{H}_{2} \mathrm{O}\right.$, $\left.\mathrm{Co}(\mathrm{SCN})_{2}, \mathrm{ZnCl}_{2}\right)$, however this did not lead to occupation of this site and products 4.154.18 and 4.19-4.21 were obtained in each case. Thus, consideration of the Hard-Soft-AcidBase Theory (HSAB) was taken into account. ${ }^{214}$ We proposed that the hardness of the aromatic and alkyl carboxylate oxygens were substantially different so that borderline hard metal cations like $\mathrm{Cu}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Co}^{2+}$ and $\mathrm{Zn}^{2+}$ could not coordinate to the harder aromatic carboxylate oxygens. It was also considered that since the ligand itself involved in counterbalancing the charge on the metal atom, that coordination to a second metal centre was restricted by the lack of anionic charges. To examine our first hypothesis both ligands were reacted with one equivalent of a harder metal cation in the form of $\mathrm{Mn}(\mathrm{OAc})_{2}$. In the case of the $\mathrm{N}-2$ isomer a crystalline solid that was of X -ray quality was obtained. The results of X-ray crystallographic analysis on $\mathbf{4 . 2 2}$ can be seen in Figure 4.20.

Figure 4.20: Subunit of 4.22 (top) and view of segment of 1-D polymeric chain (bottom).
4.22 crystallises as a 1-D polymer with a ladder like topology. Each subunit of the ladder consists of a distorted octahedral Mn (II) centre coordinated to two N atoms from the chelating pyridyl tetrazole unit, two O atoms of two bridging carboxylates from two additional 4.4(pytzda) ligands and two O atoms of two $\mathrm{H}_{2} \mathrm{O}$ molecules. Therefore, 4.4(pytzda) chelates one Mn (II) ion using two N atoms and bridges two Mn (II) ions using two 0 atoms from the same carboxylate, leaving the other uncoordinated carboxylate to form three kinds of $0-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds with three coordinated $\mathrm{H}_{2} \mathrm{O}$ molecules of
three neighbouring units with the $0 \cdots 0$ distances of 2.635(3)-2.932(2) Å. Cis elongation of the $\mathrm{Mn}(\mathrm{II})-\mathrm{N} 12 / \mathrm{N} 22$ bonds are observed, with these bond lengths being $2.3 \AA$ compared to $2.1 \AA$ for all other M-L bonds. This subunit is strikingly similar to a $2,2^{\prime}$-bipyridine 4,4'dicarboxylic acid $\mathrm{Mn}(\mathrm{II})$ helical CP reported by Li et al., ${ }^{215}$ with one carboxylate adopting an anti-syn conformation and the other remaining coordinatively free. However, the antisyn carboxylate in 4.22 has an opposite orientation compared to the complex reported by Li et al., which could explain the topological differences.

These results suggested that our hypothesis was correct: the hardness of the alkyl and aromatic carboxylates were sufficiently different and that the harder Mn (II) cation preferentially coordinated to the harder aromatic carboxylate oxygens. Consequently, it may also confirm our second hypothesis regarding the lack of anions in solution as theoretically Mn (II) should also be able to coordinate to the alkyl carboxylate. The observation of no coordination at this site indicates that it could be required to be free in order to contribute to counterbalancing the charge on the Mn (II) ion.

### 4.3.2.4 Selective Hydrolysis of Alkyl Ester

Considering the different reactivities observed between the aromatic and alkyl carboxylate, it was anticipated that employing only one equivalent of base would have an effect on the ester hydrolysis. Reacting 4.4 with one equivalent of base for 1 hour followed by the addition of $\mathrm{CuCl}_{2} 2 \mathrm{H}_{2} \mathrm{O}$ resulted in a blue crystalline solid (4.23) forming when the solution was cooled slowly. The single crystals obtained were analysed by X-ray crystallography and a subunit of the structure of 4.23 can be seen in Figure 4.21. The subunit is made up of two $\mathrm{Cu}(\mathrm{II})$ centres with distorted octahedral geometry ( $\mathrm{N}-\mathrm{Cu} 1$ posseses a bond length of $2.42 \AA$ compared to $\sim 2.02 \AA$ for all other Cu1-L bonds). Each $\mathrm{Cu}(\mathrm{II})$ centre is coordinated by two pyridyl nitrogens, two tetrazole nitrogens and two carboxylate oxygens from two additional ligands coordinating in a monodentate manner. This bonding arrangement leads to a 1-D coordination polymer which is shown in Figure 4.22. Hydrogen bonding is not as pronounced compared to previously discussed structures, however this is to be expected as there were no $\mathrm{H}_{2} \mathrm{O}$ molecules present in the structure. As seen in the structures, the alkyl ester was hydrolysed but the aromatic ester was retained. This yielded a coordination polymer with ethyl ester 'tags'. In the packing diagram (Figure 4.23) viewed along the $a$-axis, columns of pyridyl tetrazole ligands alternate between channels of these 'tags'.

Figure 4.21: Subunit of the coordination polymer 4.23.

Figure 4.22: Subsection of the bonding arrangement present in 4.23.

Figure 4.23: Packing diagram of 4.23 viewed along the $a$-axis. Channels of ethyl ester tags alternate between pyridyl tetrazole units.

A 'tag' is defined as a group or functionality that is stable and innocent (i.e. non-structuredefining) during polymer formation, but that can be transformed by a post-synthetic modification. ${ }^{216}$ This approach is shown schematically in Scheme 4.7.

Scheme 4.7: Schematic representation of the post-synthetic modification strategy for CPs.

$$
\text { Diagram adapted and edited from Burrows et al. }{ }^{216}
$$

The use of prefunctionalised linkers with tags already bonded is hampered by the fact that they are likely to interfere with CP formation. As well as this, it is not possible to use thermally labile, metal coordinating or solubility lowering functions tagged on the linker. ${ }^{217}$ Therefore, the attainment of a network like 4.23 with ethyl ester groups remaining after polymer synthesis is exceptional and offers a large number of possibilities in terms of PSM (section 1.4.3). An increasingly popular approach to forming postsynthetically modified frameworks is to undertake covalent PSM on the preformed CPs by reacting these 'tags' using organic transformations, thereby converting one solid state material into another. ${ }^{216}$ This approach, which is currently being investigated on these materials, is beyond the scope of this thesis.

The observed difference in reactivities between the aromatic and alkyl ester could be explained by the studies of Taft. ${ }^{218}$ Changes in sterics and nucleophilicity can all be viewed as substituent effects and can influence the reactivity of the groups undergoing change. Therefore, linear free energy relationships (LFER) for these kinds of substituent effects have been developed. Taft developed a scale for LFERs that reflected the steric influence of substituents on various reactions. A parameter that reflected the polar nature of the substituent $\left(\sigma^{*}\right)$ and a steric parameter $\left(E_{\mathrm{s}}\right)$ were both described. The defining reaction was the acid-catalysed hydrolysis of $\mathrm{RCO}_{2} \mathrm{Me}$, and the reference group was a methyl group. To measure the polar and steric substituent constants for the R groups, the hydrolysis was performed in both acidic and basic conditions, with the assumption that polar effects would only influence the base-catalysed hydrolysis. This assumption was made due to the fact that the basic pathway takes a neutral reactant to a negatively charged intermediate in
the rate determining step, whereas the acid-catalysed pathway takes a positively charged reactant to a positive intermediate in the rate determining step (Scheme 4.8).

Scheme 4.8: Hydrolysis of $\mathrm{RCO}_{2} \mathrm{Me}$ via the base-catalysed pathway (top) and acidcatalysed pathway (bottom).

A further assumption was that the steric effects influence the acid and base pathways equally, because they involve similar tetrahedral intermediates. Hence, the steric substituent constant, $E_{\mathrm{s}}$, was determined solely from the acid-catalysed pathway, as this would not include polar effects (Equation 4.1).

$$
\log \left(\frac{k_{s}}{k_{M e}}\right)=E_{S} \quad \text { Eqn. } 4.1
$$

The $\sigma^{*}$ values are determined from Equation 4.2, where subscripts A and B refer to the acid and base pathways and the reference reaction is the hydrolysis of $\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{CH}_{3}$. The factor of 2.48 is introduced in order to make the magnitude of these new $\sigma^{*}$ values similar to Hammett $\sigma$ values. ${ }^{219}$

$$
\begin{equation*}
\sigma *=\frac{1}{2.48}\left[\log \left(\frac{k}{k_{o}}\right)_{\mathrm{B}}-\log \left(\frac{k}{k_{o}}\right)_{\mathrm{A}}\right] \tag{Eqn. 4.2}
\end{equation*}
$$

The general Taft expression combines the steric and polar substituent scales into one equation (Eqn. 4.3), where $\rho^{*}$ and $\delta$ are the sensitivity factors for a new reaction under study to polar and steric effects, respectively.

$$
\log \left(\frac{k_{s}}{k_{M e}}\right)=\rho^{*} \sigma^{*}+\delta E_{S} \quad \text { Eqn.4. } 3
$$

Table 4.1 gives several $E_{\mathrm{s}}$ and $\sigma^{*}$ values.

Table 4.1: Selected Taft parameters.

| R group | $E_{\mathrm{s}}$ | $\sigma^{*}$ |
| :--- | :---: | :---: |
| $\mathbf{- H}$ | 1.24 | 0.49 |
| $-\mathbf{E t}$ | -0.07 | -0.10 |
| $-\mathbf{i P r}$ | -0.47 | -0.19 |
| $\mathbf{- t}-\mathbf{B u}$ | -1.54 | -0.30 |
| $\mathbf{- \mathbf { C H } _ { 2 } \mathbf { P h }}$ | -0.38 | 0.22 |
| $\mathbf{- P h}$ | -2.55 | 0.60 |

These parameters show that the rate of the hydrolysis reaction is faster when the R group is hydrogen rather than a methyl group, and that it slows as the size of the R group increases (i.e. $E_{\mathrm{s}}$ becomes more negative). ${ }^{219}$ Although pyridine was not included in these studies, one can compare it to the phenyl group, which would hydrolyse at a slower rate relative to the R group being a $\mathrm{CH}_{2}$ or a $\mathrm{CH}_{2} \mathrm{Ph}$ group. The rate of hydrolysis of the pyridyl ester must be sufficiently slow in order for yields of $>90 \%$ to result for complex 4.22.

### 4.3.3 EPR Spectral Studies on Cu (II) Compounds

The principles of EPR spectroscopy were previously discussed in section 3.3.3.2. The Xband EPR spectra of 4.15 and 4.23 were measured in the solid state as powders at room temperature. Figure 4.24 displays the EPR spectrum of 4.15, which resembles an isotropic signal, where $g_{\mathrm{x}}=g_{\mathrm{y}}=g_{\mathrm{z}}$. It was observed that this signal could have been overlapping with another signal, however it was proposed that the crystallinity of the sample could perturb the signal (samples were ground however crystalline particles always remained). Alternatively, carrying out EPR spectroscopy at a higher resolution might have further resolved this signal into a rhombic signal. The extracted $g$ factor (2.157) was typical of a transition metal unpaired electron as it was much greater than the free electron $g$ value. ${ }^{176}$ An isotropic signal implies that the three principle axes are the same and on examination of the bond lengths around the $\mathrm{Cu}(\mathrm{II})$ centres (which are all $\sim 2 \AA$ ) this was observed to be in agreement with the crystal structure obtained.

Figure 4.24: Room temperature 9.63 GHz EPR spectrum of a powder sample of 4.15. $g_{\mathrm{x}}=$ $g_{\mathrm{y}}=g_{\mathrm{z}}=2.157$.

The EPR spectrum of $\mathbf{4 . 2 3}$ is shown in Figure 4.25. The spectrum displays axial symmetry with the abstracted $g$ factors exhibiting the trend $g_{\mathrm{z}}>g_{\mathrm{x}} \sim g_{\mathrm{y}}$, indicating that the unpaired electron lies predominantly in the $\mathrm{d}_{x^{2}-y^{2}}$ orbital. This is in agreement with the crystal structure obtained and is consistent with axially elongated octahedral complexes.

Figure 4.25: Room temperature 9.63 GHz EPR spectrum of a powder sample of 4.23. $g_{\mathrm{xy}}$; $g_{z}=2.042 ; 2.336$.

### 4.3.4 Luminescence studies

As discussed in section 3.3.4, $\mathrm{d}^{10}$ metal complexes exhibit excellent photoluminescent properties. ${ }^{220}$ To investigate the luminescence properties of the asymmetric carboxylate functionalised pyridyl tetrazoles and their Zn (II) complexes, the photoluminescence measurements of 4.4 (pytzdaH) and 4.21 were carried out in the solid state at room temperature by collaborators in the Laboratory of Synthetic Bioinorganic Chemistry, University of Crete. The spectra obtained can be seen in Figure 4.26. It can be seen that they exhibit fluorescence signals with the emission maxima at 425 nm for the free acid and 438 nm for the $\mathrm{Zn}(\mathrm{II})$ complex, with $\lambda_{\text {ex }}=350 \mathrm{~nm}$. Compared to the spectra of the free
ligand, the spectrum of 4.21 is similar in terms of band shape, hence these emission bands can be attributed to an intraligand emission state. ${ }^{146}$ The observed red shift of 13 nm may arise from the coordination effect of the $\mathrm{Zn}(\mathrm{II})$ centre to the ligand. ${ }^{146}$ The chelation of the ligand to the metal ion effectively increases the conformational rigidity of the ligand reducing energy loss by vibrational relaxation, thus enhancing fluorescence. ${ }^{146}$ These results indicate that these compounds may be good candidates for light emitting materials.

Figure 4.26: Solid state emission spectra for free ligands 4.4(pytzdaH) and Zn (II) complex 4.21. Excitation wavelength was 350 nm .

### 4.4 Conclusions

This chapter dealt with the further development of the organic linkers discussed in Chapter 3 into second generation organic linkers, and their incorporation in the formation of coordination polymers. Another carboxylate group on the pyridine ring was proposed to enhance the ability of the pyridyl tetrazole unit to form novel diverse high dimensional frameworks. Hence, 4.3 and 4.4 were synthesised starting from isonicotinic acid. Taking advantage of the reactivity of pyridine N -oxides, a nitrile group was successfully substituted at the 2 -position of the ring, allowing a 1,3-dipolar cycloaddition to be undertaken, which was subsequently followed by alkylation to yield 4.3 and 4.4.
4.3 and 4.4 were converted to their respective carboxylate derivatives 4.3 (pytzda) and 4.4(pytzda) in situ with aqueous NaOH employing conventional nonsolvothermal heating. Metal salts were added to the solutions and these were allowed to cool slowly. Crystalline solids formed after varying amounts of times (minutes to weeks). These often colourful materials were analysed by IR, EPR and NMR spectroscopies, magnetic moment, elemental
analysis, and in some cases X-ray crystallography. On examination of the effect of regioisomerism on final structures, there are clear consequences observed. N-1 substituted $\mathbf{4 . 3}$ (pytzda) formed 1-D coordination polymers, whereas $\mathbf{4 . 4}$ (pytzda) formed isolated dinuclear structures. This is tentatively attributed to the ease of which the $\mathrm{N}-2$ isomer can suit the coordination geometry requirements of the metal ion by orientating the pendant carboxylate almost perpendicular to itself. The $\mathrm{N}-1$ isomer could possibly be restricted from doing so due to its position, therefore it is much more stable pointing away from itself, allowing a 1-D chain to propagate.

In all cases, employing borderline hard Lewis acids $\left(\mathrm{Cu}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Co}^{2+}, \mathrm{Zn}^{2+}\right)$ resulted in the aromatic carboxylates remaining free in the complexes. This offers exciting possibilities for post-synthetic metalation. Post-synthetic metalation is a promising new avenue of post-synthetic modification that has developed in recent years, and future work on these compounds would involve taking advantage of these free chelation sites for metal insertion and to investigate their gas absorption and gas separation abilities, as well as catalytic applications. Thus far, attempts to saturate both the alkyl and aromatic carboxylate sites have failed which we believe could be due to two reasons. Firstly, the hardness of the metal ions utilised might not be appropriate for the aromatic carboxylate oxygens, which could be harder donor atoms compared to the alkyl carboxylate oxygens. This was somewhat confirmed by complexing 4.4 (pytzda) with $\mathrm{Mn}(\mathrm{OAc})_{2}$ and achieving coordination with the aromatic carboxylate and not the alkyl carboxylate. Secondly, since the ligands are often themselves counterbalancing the charge on the first row metal complexes, it may be that no further metal insertion could be possible if anions are dissociating. Future work would involve circumventing this issue by the addition of a source of anions if this is indeed the reason why metal insertion is not occurring.

In solid state fluorescence studies, zinc complex 4.21 showed significant enhancement in emission, further indicating that diamagnetic pyridyl tetrazole complexes could be good light emitting materials; an aspect that will be further studied in future work.

In contrast to the prolific bipyridine dicarboxylate ligands used in CP synthesis, studies on asymmetric ligands like $\mathbf{4 . 3}$ (pytzda) and $\mathbf{4 . 4 ( p y t z d a )}$ are less developed. However as demonstrated here, the potential to obtain interesting and diverse structures with intriguing properties with such asymmetric structures is great. Overall, $\mathbf{4 . 3}$ (pytzda) and 4.4(pytzda) proved to be novel versatile ligands in the formation of CPs and dinuclear clusters, and indicate that studies on asymmetric ligands should be investigated further.

### 4.5 Experimental

### 4.5.1 Instrumentation

${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR ( $\delta \mathrm{ppm}$; $J \mathrm{~Hz}$ ) spectra were recorded on a Bruker Avance 300 MHz NMR spectrometer using saturated $\mathrm{CDCl}_{3}$ or $d_{6}$-DMSO solutions with $\mathrm{SiMe}_{4}$ reference, unless indicated otherwise, with resolutions of 0.18 Hz and 0.01 ppm , respectively. Infrared spectra ( $\mathrm{cm}^{-1}$ ) were recorded as KBr discs or liquid films between NaCl plates using a Perkin Elmer System 2000 FT-IR spectrometer. Solution UV-Vis spectra were recorded using HPLC grade solvents using a Unicam UV 540 spectrometer. Melting point analyses were carried out using a Stewart Scientific SMP 1 melting point apparatus and are uncorrected. Electrospray (ESI) mass spectra were collected on an Agilent Technologies 6410 Time of Flight LC/MS. Compounds were dissolved in acetonitrile:water (1:1) solutions containing $0.1 \%$ formic acid, unless otherwise stated. The interpretation of mass spectra was made with the help of the program "Agilent Masshunter Workstation Software". Magnetic susceptibility measurements were carried out at room temperature using a Johnson Matthey Magnetic Susceptibility Balance with $\left[\mathrm{HgCo}(\mathrm{SCN})_{4}\right]$ as reference. EPR spectra were recorded on a Bruker Elexsys E500 spectrometer, operated at the Xband and equipped with an Oxford Instruments cryostat. Solid state UV-Vis measurements were carried out in the Synthetic Bioinorganic Chemistry Laboratory of the University of Crete and were performed on a Perkin Elmer Lambda 950 UV/Vis spectrometer. Solid state fluorescence spectra were also carried out in this laboratory and were recorded on a Jobin-Yvon Horiba, Fluoro Max-P (SPEX) fluorescence spectrometer, with excitation from a cw Xenon arc lamp. Microanalyses were carried out at the Microanalytical Laboratory of the National University of Ireland Maynooth, using a Thermo Finnigan Elementary Analyzer Flash EA 1112. The results were analysed using the Eager 300 software. All crystal structures resulting from this work were solved by Dr. John Gallagher (Dublin City University) using an Oxford Diffraction Gemini-S Ultra diffractometer at 294(1) K. Structures were solved using the SHELXS97 direct methods program. Molecular diagrams were generated using Mercury software. Starting materials were commercially obtained and used without further purification. Solvents used were of HPLC grade.
Caution! Nitrogen-rich compounds such as tetrazole derivatives are used as components for explosive mixtures. In our laboratory, the reactions described were run on a few gram scale, and no problems were encountered. However, great caution should be exercised when heating or handling compounds of this type.

### 4.5.2 Synthesis of Diester Pyridyl Tetrazoles 4.3 and 4.4

### 4.5.2.1 4-(Methoxycarbonyl)pyridine (4.8a)

Sulfuric acid ( $0.24 \mathrm{~mL}, 4.46 \mathrm{mmol}$ ) was added dropwise to a suspension of isonicotinic acid ( $0.50 \mathrm{~g}, 4.06 \mathrm{mmol})$ in $\mathrm{MeOH}(10 \mathrm{~mL})$ at $0^{\circ} \mathrm{C}$. The solution was then heated to reflux for 18 h . After this time the reaction was cooled to room temperature and the solvent was removed under reduced pressure. The remaining residue was dissolved in deionised H 2 O , cooled to $0{ }^{\circ} \mathrm{C}$ and the pH was adjusted to pH 8 with $\mathrm{K}_{2} \mathrm{CO}_{3}$. After extraction with chloroform ( $3 \times 10 \mathrm{~mL}$ ), the combined organic layers were washed with brine, dried over $\mathrm{MgSO}_{4}$ and filtered. The filtrate was concentrated under reduced pressure to yield a yellow oil ( $0.55 \mathrm{~g}, 98 \%$ ). IR (neat): $v=2955,1951,1732,1599,1561,1494,1437,1407,1326$,
 $2 \mathrm{H}, J=6.0 \mathrm{~Hz}$, pyr-H), $7.84\left(\mathrm{~d}, 2 \mathrm{H}, J=6.0 \mathrm{~Hz}\right.$, pyr-H), $3.96\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=165.4(\mathrm{C}=0), 150.5,137.2,122.7,52.6\left(\mathrm{CH}_{3}\right) \mathrm{ppm}$.

The acquired data are in agreement with literature reported values. ${ }^{202}$

### 4.5.2.2 4-(Ethoxycarbonyl)pyridine (4.8b)

Sulfuric acid ( $0.48 \mathrm{~mL}, 8.92 \mathrm{mmol}$ ) was added dropwise to a suspension of isonicotinic acid $(1.00 \mathrm{~g}, 8.12 \mathrm{mmol})$ in EtOH $(10 \mathrm{~mL})$ at $0^{\circ} \mathrm{C}$. The solution was then heated to reflux for 18 h . After this time the reaction was cooled to room temperature and the solvent was removed under reduced pressure. The remaining residue was dissolved in deionised $\mathrm{H}_{2} \mathrm{O}$, cooled to $0{ }^{\circ} \mathrm{C}$ and the pH was adjusted to pH 8 with $\mathrm{K}_{2} \mathrm{CO}_{3}$. After extraction with $\mathrm{CHCl}_{3}(3$ $\times 10 \mathrm{~mL}$ ), the combined organic layers were washed with brine, dried over magnesium sulfate and filtered. The filtrate was concentrated under reduced pressure to yield a yellow oil ( $0.75 \mathrm{~g}, 62 \%$ ). IR (DCM film): $v=2984,2939,1728,1597,1563,1466,1447$, 1409, 1368, 1324, 1281, 1214, 1174, 1119, 1064, 1021, 993, 874, 852, $758 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.72(\mathrm{~d}, 2 \mathrm{H}, J=6.0 \mathrm{~Hz}$, pyr-H), $7.79(\mathrm{~d}, 2 \mathrm{H}, J=6.0 \mathrm{~Hz}, \mathrm{pyr}-\mathrm{H}), 4.36(\mathrm{q}, 2 \mathrm{H}, J=$
$\left.7.1 \mathrm{~Hz}, \mathrm{OCH}_{2}\right), 1.35\left(\mathrm{t}, 3 \mathrm{H}, \mathrm{J}=7.1 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right): \delta=163.8(\mathrm{C}=0), 147.6$, 140.3, 124.2, $62.4\left(\mathrm{OCH}_{2}\right), 14.1\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{8} \mathrm{H}_{9} \mathrm{NO}_{2}[\mathrm{M}+\mathrm{H}]^{+}$ 152.0706, found 152.0706.

NMR and IR data are in agreement with literature data. ${ }^{221}$

### 4.5.2.3 4-(Methoxycarbonyl)pyridine-1-oxide (4.9a)

0.49 mL of a $\mathrm{H}_{2} \mathrm{O}_{2}$ solution ( $35 \% \mathrm{w} / \mathrm{w}$ ) was added to a solution of 4.8 a ( $0.31 \mathrm{~g}, 2.18 \mathrm{mmol}$ ) in glacial acetic acid ( 2.25 mL ). The mixture was heated at $75^{\circ} \mathrm{C}$ for 20 h . The mixture was concentrated under reduced pressure and the resulting residue was taken up in $\mathrm{H}_{2} \mathrm{O}$ and made alkaline $(\mathrm{pH} 8)$ with $\mathrm{K}_{2} \mathrm{CO}_{3}$. This basic solution was then extracted with EtOAc ( $3 \times$ 10 mL ) and the combined extracts were washed with brine and dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$. Evaporation of the solvent yielded a pale yellow solid ( $0.32 \mathrm{~g}, 97 \%$ ). m.p. 123-125 ${ }^{\circ} \mathrm{C}\left(\right.$ lit. $\left.118-120^{\circ} \mathrm{C}\right) .{ }^{222}$ IR (KBr): $v=3120,3051,1716,1610,1484,1434,1299,1262,1190$, $1169,1118,1092,1024,957,858,771,683,634 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta=8.21(\mathrm{~d}, 2 \mathrm{H}, \mathrm{J}=$ 7.2 Hz, pyr-H), $7.87\left(\mathrm{~d}, 2 \mathrm{H}, J=7.2 \mathrm{~Hz}\right.$, pyr-H), $3.95\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=$ 163.8 (C=O), 139.5, 126.6, 126.4, $52.8\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{7} \mathrm{H}_{7} \mathrm{NO}_{3}[\mathrm{M}+\mathrm{H}]^{+}$ 154.0499, found 154.0504 .

The acquired data are in agreement with literature reported values. ${ }^{207}$

### 4.5.2.4 4-(Ethoxycarbonyl)pyridine-1-oxide (4.9b)

4.48 mL of a $\mathrm{H}_{2} \mathrm{O}_{2}$ solution ( $35 \% \mathrm{w} / \mathrm{w}$ ) was added to a solution of $4.8 \mathrm{~b}(3.33 \mathrm{~g}, 22.04$ mmol) in glacial acetic acid ( 20.52 mL ). The mixture was heated at $75{ }^{\circ} \mathrm{C}$ for 24 h . The
mixture was concentrated under reduced pressure and the resulting residue was taken up in $\mathrm{H}_{2} \mathrm{O}$ and made alkaline ( pH 8 ) with $\mathrm{K}_{2} \mathrm{CO}_{3}$. This basic solution was then extracted with DCM ( $3 \times 10 \mathrm{~mL}$ ) and the combined extracts were washed with brine and dried over anhydrous $\mathrm{MgSO}_{4}$. Evaporation of the solvent yielded a yellow solid. ( $3.27 \mathrm{~g}, 89 \%$ ). m.p. $59-60{ }^{\circ} \mathrm{C}$ (lit. $58{ }^{\circ} \mathrm{C}$ ). ${ }^{223}$ IR (KBr): $v=3079,2981,1720,1613,1552,1474,1458,1443$, 1369, 1281, 1257, 1167, 1127, 1106, 1092, 1016, 873, 860, $771 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=$ $8.22\left(\mathrm{~d}, 2 \mathrm{H}, J=7.2 \mathrm{~Hz}\right.$, pyr-H), $7.88\left(\mathrm{~d}, 2 \mathrm{H}, J=7.2 \mathrm{~Hz}\right.$, pyr-H), $4.40\left(\mathrm{q}, 2 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{OCH}_{2}\right)$, $1.40\left(\mathrm{t}, 3 \mathrm{H}, \mathrm{J}=7.1, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta=163.3(\mathrm{C}=0), 139.4,126.8,126.3,61.9$ $\left(\mathrm{OCH}_{2}\right), 14.19\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{8} \mathrm{H}_{9} \mathrm{NO}_{3}[\mathrm{M}+\mathrm{H}]^{+} 168.0655$, found 168.0655 .

The NMR and IR data acquired are in agreement with literature values. ${ }^{223}$

### 4.5.2.5 Methyl-2-cyanoisonicotinate (4.10a)

A reaction mixture of $4.9 \mathrm{a}(0.20 \mathrm{~g}, 1.30 \mathrm{mmol})$, $\mathrm{DMCC}(0.12 \mathrm{~mL}, 1.30 \mathrm{mmol})$ and $\mathrm{Zn}(\mathrm{CN})_{2}$ $(0.23 \mathrm{~g}, 1.96 \mathrm{mmol})$ in toluene ( 15 mL ) was heated to reflux under an argon atmosphere for 6 h . The reaction mixture was cooled to room temperature and deionised $\mathrm{H}_{2} \mathrm{O}(10 \mathrm{~mL})$ was added, and stirring was continued for 15 min . The organic layer was separated, washed with brine, dried over $\mathrm{MgSO}_{4}$ and concentrated under reduced pressure to yield an orange solid ( $0.21 \mathrm{~g}, 65 \%$ ) which required no further purification. m.p. $100-103{ }^{\circ} \mathrm{C}$. IR (KBr): $v=2958,2852,2237,1726,1441,1397,1298,1209,1116,974,934,882,869,765$ $\mathrm{cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.90(\mathrm{dd}, 1 \mathrm{H}, J=4.9,0.8 \mathrm{~Hz}, \mathrm{pyr}-\mathrm{H}), 8.24(\mathrm{dd}, 1 \mathrm{H}, J=1.5,0.8 \mathrm{~Hz}$, pyr-H), 8.07 (dd, $1 \mathrm{H}, J=4.9,1.5 \mathrm{~Hz}$, pyr-H), $4.01\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=$ 162.6 (C=O), 151.0, 137.7, 133.8, 126.6, 125.0, $115.5(\mathrm{CN}), 52.3\left(\mathrm{OCH}_{3}\right) \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{8} \mathrm{H}_{6} \mathrm{~N}_{2} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}]^{+} 163.0502$, found 163.0509 .

NMR data is in agreement with literature data. ${ }^{208}$

### 4.5.2.6 Ethyl-2-cyanoisonicotinate (4.10b)

A reaction mixture of $\mathbf{4 . 9 b}(3.64 \mathrm{~g}, 21.82 \mathrm{mmol})$, DMCC ( $3.01 \mathrm{~mL}, 32.73 \mathrm{mmol}$ ) and $\mathrm{Zn}(\mathrm{CN})_{2}(3.84 \mathrm{~g}, 32.73 \mathrm{mmol})$ in toluene ( 40 mL ) was heated under reflux under an argon atmosphere for 2 h . The reaction mixture was cooled to room temperature and $\mathrm{H}_{2} \mathrm{O}$ (30 mL ) was added, and stirring was continued for 15 min . The organic layer was separated, washed with brine, dried over $\mathrm{MgSO}_{4}$ and concentrated under reduced pressure to yield a brown solid. This was then passed through a silica plug using EtOAc:Pet. Ether in a $2: 1$ ratio as the eluent yielding a yellow oil which solidified on ice. Orange solid ( $3.28 \mathrm{~g}, 85 \%$ ). m.p. 39-40 ${ }^{\circ} \mathrm{C}$ (lit. $42-44^{\circ} \mathrm{C}$ )..$^{224} \mathrm{IR}$ (KBr): $v=2988,2964,2238,1728,1597,1557,1470$, 1402, 1393, 1370, 1298, 1281, 1202, 1113, 1015, 990, 918, 890, 862, 763, $686 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta=8.90(\mathrm{dd}, 1 \mathrm{H}, J=4.9,0.9 \mathrm{~Hz}$, pyr-H), $8.25(\mathrm{dd}, 1 \mathrm{H}, J=1.5,0.9 \mathrm{~Hz}$, pyr-H), $8.10(\mathrm{dd}, 1 \mathrm{H}, J=4.9,1.5 \mathrm{~Hz}, \mathrm{pyr}-\mathrm{H}), 4.47\left(\mathrm{q}, 2 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{OCH}_{2}\right), 1.44(\mathrm{t}, 3 \mathrm{H}, J=7.1 \mathrm{~Hz}$, $\mathrm{CH}_{3}$ ) ppm. ${ }^{13} \mathrm{C}^{\mathrm{NMR}}\left(\mathrm{CDCl}_{3}\right): \delta=163.1(\mathrm{C}=0), 151.9,139.0,134.7,127.6,126.1,116.6(\mathrm{CN})$, $62.6\left(\mathrm{OCH}_{2}\right), 14.1\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{~N}_{2} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}]^{+} 177.0659$, found 177.0659 .

NMR data is in agreement with literature data. ${ }^{224}$

### 4.5.2.7 Methyl-2(1H-tetrazol-5-yl)isonicotinate (4.11a)

4.10a ( $0.20 \mathrm{~g}, 1.25 \mathrm{mmol}$ ), $\mathrm{NaN}_{3}(0.09 \mathrm{~g}, 1.38 \mathrm{mmol}), \mathrm{NH}_{4} \mathrm{Cl}(0.07 \mathrm{~g}, 1.38 \mathrm{mmol})$ and LiCl ( $0.03 \mathrm{~g}, 0.62 \mathrm{mmol}$ ) were heated at $110{ }^{\circ} \mathrm{C}$ in DMF for 12 h . The reaction mixture was filtered and the filtrate concentrated under reduced pressure. The residue was then taken up in deionised $\mathrm{H}_{2} \mathrm{O}$ and 1 M HCl was added slowly until precipitation initiated. The mixture was then filtered and the solid dried. Brown solid ( $0.15 \mathrm{~g}, 62 \%$ ). m.p. $163-166^{\circ} \mathrm{C}$. IR (KBr): $v=3071,2922,1724,1547,1438,1416,1393,1336,1295,1270,1247,1198$, 1173, 1054, 1031, 967, 755, $746 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO): $\delta=9.01(\mathrm{~d}, 1 \mathrm{H}, J=4.9 \mathrm{~Hz}$, pyr-
H), 8.56 (s, 1 H, pyr-H), $8.04\left(\mathrm{~d}, 1 \mathrm{H}, J=4.9 \mathrm{~Hz}\right.$, pyr-H), $4.03\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR ( $d_{6}$-DMSO): $\delta=164.3$ (C=O), 153.3, 151.4, 144.9, 138.6, 124.5, 121.0, $53.0\left(\mathrm{OCH}_{3}\right) \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{8} \mathrm{H}_{7} \mathrm{~N}_{5} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}]^{+}$206.0673, found 206.0677.

### 4.5.2.8 Ethyl-2(1H-tetrazol-5-yl)isonicotinate (4.11b)

4.10b ( $2.28 \mathrm{~g}, 12.93 \mathrm{mmol}$ ), $\mathrm{NaN}_{3}(0.93 \mathrm{~g}, 14.22 \mathrm{mmol}), \mathrm{NH}_{4} \mathrm{Cl}(0.76 \mathrm{~g}, 14.22 \mathrm{mmol})$ and LiCl ( $0.27 \mathrm{~g}, 6.47 \mathrm{mmol}$ ) were heated at $110^{\circ} \mathrm{C}$ in DMF ( 20 mL ) for 12 h . The reaction mixture was cooled to room temperature, filtered and the filtrate was concentrated under reduced pressure. The remaining residue was redissolved in deionised $\mathrm{H}_{2} \mathrm{O}$ and 1 M HCl was added dropwise until precipitation was initiated. When the formation of a precipitate ceased, the mixture was filtered. The collected precipitate was recrystallised from hot EtOH, yielding white crystals which were filtered off and washed with cold EtOH. White crystalline solid ( $2.13 \mathrm{~g}, 75 \%$ ). m.p. $186-191{ }^{\circ} \mathrm{C}$. IR (KBr): $v=3085,2900,2751,1721$, 1613, 1566, 1468, 1445, 1421, 1384, 1367, 1317, 1289, 1248, 1216, 1140, 1120, 1025, 1000, 896, 865, 762, 745, 726, $683 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO): $\delta=9.01$ (d, $1 \mathrm{H}, J=4.9 \mathrm{~Hz}$, pyr-H), 8.56 (s, 1 H, pyr-H), 8.04 (d, $1 \mathrm{H}, J=4.9 \mathrm{~Hz}$, pyr-H), $4.43\left(\mathrm{q}, 2 \mathrm{H}, J=7.2 \mathrm{~Hz}, \mathrm{OCH}_{2}\right.$ ), $1.38\left(\mathrm{t}, 3 \mathrm{H}, J=7.2 \mathrm{~Hz}, \mathrm{CH}_{3}\right.$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $d_{6}$-DMSO): $\delta=163.7$ (C=O), 154.5, 151.4, 144.8, 138.8, 124.6, 121.0, $62.0\left(\mathrm{OCH}_{2}\right), 13.9\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{9} \mathrm{H}_{10} \mathrm{~N}_{5} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}]^{+}$ 220.0829 , found 220.0830 .

### 4.5.2.9 Synthesis of 4.3 and 4.4

4.11b ( $1.30 \mathrm{~g}, 5.93 \mathrm{mmol}$ ) was heated to reflux with $\mathrm{K}_{2} \mathrm{CO}_{3}(0.90 \mathrm{~g}, 6.52 \mathrm{mmol})$ in MeCN $(20 \mathrm{~mL})$ for 30 min . Ethyl bromoacetate ( $1.09 \mathrm{~g}, 6.52 \mathrm{mmol}$ ) was added to the mixture and the reaction was further heated to reflux for 24 h . The reaction was then cooled to room temperature and filtered and the filtrate was concentrated under reduced pressure. The
remaining residue which consisted of two isomers was separated by column chromatography using Pet. Ether:EtOAc (2:1) as the eluent. The two regioisomers were recrystallised from a mixture of DCM and Pet. Ether.

### 4.5.2.9.1 Ethyl 2-(1-(2-ethoxy-2-oxoethyl)-1H-tetrazol-5-yl)isonicotinate (4.3)

White solid ( $0.65 \mathrm{~g}, 37 \%$ ). m.p. $78-80^{\circ} \mathrm{C}$. IR (KBr): $v=2980,2908,1758,1733,1604,1537$, 1433, 1392, 1275, 1301, 1253, 1214, 1143, 1121, 1102, 1020, 993, 875, 772, 751, 722, $707,681,590 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.97(\mathrm{dd}, 1 \mathrm{H}, J=1.5,0.9 \mathrm{~Hz}$, pyr-H), $8.80(\mathrm{dd}, 1 \mathrm{H}$, $J=5.0,0.9 \mathrm{~Hz}$, pyr-H), $8.01\left(\mathrm{dd}, 1 \mathrm{H}, J=5.0,1.5 \mathrm{~Hz}\right.$, pyr-H), $5.74\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CH}_{2}\right.$-tet), $4.47(\mathrm{q}, 2$ $\left.\mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{2}\right), 4.19\left(\mathrm{q}, 2 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{2}\right), 1.44\left(\mathrm{t}, 3 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{3}\right), 1.19(\mathrm{t}, 3 \mathrm{H}, J=$ $\left.7.1 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=165.8(\mathrm{C}=0), 163.9(\mathrm{C}=0), 151.8\left(\mathrm{CN}_{4}\right), 150.0$, 145.5, 139.6, 124.7, 123.5, $62.4\left(\mathrm{OCH}_{2}\right), 62.2\left(\mathrm{OCH}_{2}\right), 51.1\left(\mathrm{CH}_{2}\right.$-tet $), 14.2\left(\mathrm{CH}_{3}\right), 14.0\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{13} \mathrm{H}_{16} \mathrm{~N}_{5} \mathrm{O}_{4}[\mathrm{M}+\mathrm{H}]^{+} 306.1197$, found 306.1195.

### 4.5.2.9.2 Ethyl 2-(2-(2-ethoxy-2-oxoethyl)-2H-tetrazol-5-yl)isonicotinate (4.4)

White solid ( $0.72 \mathrm{~g}, 40 \%$ ). m.p. $89-92^{\circ} \mathrm{C}$. IR (KBr): $v=3075,2994,2952,1756,1716,1605$, 1564, 1473, 1427, 1376, 1355, 1299, 1259, 1220, 1201, 1174, 1110, 1098, 1050, 1025, $886,874,783,763,682 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.94(\mathrm{dd}, 1 \mathrm{H}, J=4.9,0.8 \mathrm{~Hz}$, pyr-H), $8.80\left(\mathrm{dd}, 1 \mathrm{H}, J=1.6,0.8 \mathrm{~Hz}\right.$, pyr-H), $7.98\left(\mathrm{dd}, 1 \mathrm{H}, J=4.9,1.6 \mathrm{~Hz}\right.$, pyr-H), $5.54\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CH}_{2}-\right.$ tet), 4.47 (q, $\left.2 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{2}\right), 4.29\left(\mathrm{q}, 2 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{2}\right), 1.45\left(\mathrm{t}, 3 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{3}\right)$, $1.29\left(\mathrm{t}, 3 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=164.7(\mathrm{C}=0), 164.7\left(\mathrm{CN}_{4}\right), 163.9$ ( $\mathrm{C}=0$ ), 147.4, 139.1, 124.2, 121.8, $62.8\left(\mathrm{OCH}_{2}\right), 62.1\left(\mathrm{OCH}_{2}\right), 53.6\left(\mathrm{CH}_{2}\right.$-tet), $14.2\left(\mathrm{CH}_{3}\right), 14.0$ $\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{13} \mathrm{H}_{16} \mathrm{~N}_{5} \mathrm{O}_{4}[\mathrm{M}+\mathrm{H}]^{+} 306.1197$, found 306.1197.

### 4.5.2.10 2-(1-(Carboxymethyl)-1H-tetrazol-5-yl)isonicotinic acid (4.3(pytzdaH))

4.3 ( $0.30 \mathrm{~g}, 0.98 \mathrm{mmol}$ ) was dissolved in EtOH ( 20 mL ). $\mathrm{NaOH}(0.20 \mathrm{~mL}, 10 \mathrm{M} \mathrm{NaOH}$ ) was added to the solution and was heated to reflux overnight. The reaction mixture was concentrated under reduced pressure and the remaining residue was then dissolved in deionised $\mathrm{H}_{2} \mathrm{O}(3 \mathrm{~mL}) .1 \mathrm{M} \mathrm{HCl}$ was added to the solution whilst stirring until precipitation commenced. The mixture was then allowed to stir at room temperature for 1 h , filtered and the precipitate was washed with $\mathrm{H}_{2} \mathrm{O}$. White solid ( 0.18 g , $75 \%$ ). m.p. $165-170{ }^{\circ} \mathrm{C}$. IR $(\mathrm{KBr}): v=3431,3014,2573,1726,1640,1548,1432,1403,1271,1246,1123,1092,912$, 819, 783, 747, 730, 673, $546 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO): $\delta=8.94$ (dd, $1 \mathrm{H}, J=4.9,0.8 \mathrm{~Hz}$, pyr-H), 8.64 (dd, $1 \mathrm{H}, J=1.5,0.8 \mathrm{~Hz}, \operatorname{pyr}-\mathrm{H}$ ), 8.02 (dd, $1 \mathrm{H}, J=4.9,1.5 \mathrm{~Hz}, \operatorname{pyr}-\mathrm{H}$ ), 5.75 (s, 2 $\mathrm{H}, \mathrm{CH}_{2}$-tet) ppm. ${ }^{13} \mathrm{C}$ NMR ( $d_{6}$-DMSO): $\delta=167.8$ (C=0), 165.1 (C=0), $151.7\left(\mathrm{CN}_{4}\right), 150.9$, 144.8, 140.1, 124.7, 122.3, 50.9 ( $\mathrm{CH}_{2}$-tet) ppm. ESI-HRMS: calcd. for $\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{~N}_{5} \mathrm{O}_{4}[\mathrm{M}+\mathrm{H}]^{+}$ 250.0571 , found 250.0567 .

### 4.5.2.11 2-(2-(Carboxymethyl)-2H-tetrazol-5-yl)isonicotinic acid (4.4(pytzdaH))

4.4 ( $0.30 \mathrm{~g}, 0.98 \mathrm{mmol}$ ) was dissolved in EtOH ( 20 mL ). $\mathrm{NaOH}(0.20 \mathrm{~mL}, 10 \mathrm{M} \mathrm{NaOH}$ ) was added to the solution and was heated under reflux for 4 h . The reaction mixture was concentrated under reduced pressure and the remaining residue was then dissolved in deionised $\mathrm{H}_{2} \mathrm{O}(3 \mathrm{~mL}) .1 \mathrm{M} \mathrm{HCl}$ was added to the solution whilst stirring until precipitation commenced. The mixture was then allowed to stir at room temperature for 1 h , filtered and the precipitate was washed with $\mathrm{H}_{2} \mathrm{O}$. White solid ( 0.16 g, $66 \%$ ). m.p. 225-230 ${ }^{\circ} \mathrm{C}$. IR $(\mathrm{KBr}): v=3421,3026,2901,2595,2508,1744,1708,1615,1565,1474,1416,1396,1372$, $1286,1261,1232,1199,1178,1118,1095,1004,876,856,818,761,722,666,645 \mathrm{~cm}^{-1}$. ${ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO): $\delta=8.95$ (dd, $1 \mathrm{H}, J=4.9,0.8 \mathrm{~Hz}, \operatorname{pyr}-\mathrm{H}$ ), $8.52(\mathrm{dd}, 1 \mathrm{H}, J=1.5,0.8 \mathrm{~Hz}$,
pyr-H), 7.98 (dd, $1 \mathrm{H}, J=4.9,1.5 \mathrm{~Hz}$, pyr-H), $5.80\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CH}_{2}\right.$-tet) ppm. ${ }^{13} \mathrm{C}$ NMR ( $d_{6}$-DMSO): $\delta=167.3(\mathrm{C}=0), 165.4(\mathrm{C}=0), 163.7\left(\mathrm{CN}_{4}\right), 151.4,146.9,139.6,124.1,121.0,53.8\left(\mathrm{CH}_{2}\right.$-tet $)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{~N}_{5} \mathrm{O}_{4}[\mathrm{M}+\mathrm{H}]^{+} 250.0571$, found 250.0559 .

### 4.5.3 Metal Complexation Reactions

### 4.5.3.1 Complexes of Diester Pyridyl Tetrazoles 4.3 and 4.4

### 4.5.3.1.1 $\left[\mathrm{Cu}(4.3) \mathrm{Cl}_{2}\right]_{2}(4.12)$

$4.3(0.10 \mathrm{~g}, 0.33 \mathrm{mmol})$ was dissolved in $\mathrm{MeOH}(10 \mathrm{~mL})$. A solution of $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}(0.06 \mathrm{~g}$, 0.33 mmol ) in $\mathrm{MeOH}(5 \mathrm{~mL}$ ) was added to this solution and the reaction was heated under reflux for 2 h . The solution was allowed to stand until the solvent evaporated off to leave a green oily residue. MeOH was added to this residue and allowed to stand again producing a green crystalline solid which was filtered and dried. Green crystalline solid (0.06 g, $43 \%$ ). $\mathrm{C}_{26} \mathrm{H}_{30} \mathrm{Cu}_{2} \mathrm{Cl}_{4} \mathrm{~N}_{10} \mathrm{O}_{8}$ : calcd. C 35.51, H 3.44, N 15.93\%; found C 35.01, H3.27, N 14.96\%. IR (KBr): $v=3437,3414,2989,2918,1749,1728,1624,1558,1457,1390,1371$, $1293,1262,1234,1147,1124,1013,867,794,713,688 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 880 \mathrm{~nm}, \varepsilon=90$ $\mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 1.78 B.M.

### 4.5.3.2 $\left[\mathrm{Cu}(4.4) \mathrm{Cl}_{2}\right](4.13)$

$4.4(0.20 \mathrm{~g}, 0.65 \mathrm{mmol})$ was dissolved in $\mathrm{MeOH}(15 \mathrm{~mL})$. A solution of $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}(0.11 \mathrm{~g}$, 0.65 mmol ) in $\mathrm{MeOH}(10 \mathrm{~mL})$ was added to the ligand solution and heated under reflux for 2 h . The solution was allowed to stand for several days at room temperature. The resulting solids were collected by filtration. Crystalline blue solid ( $0.04 \mathrm{~g}, 18 \%$ ). $\mathrm{C}_{22} \mathrm{H}_{22} \mathrm{Cl}_{2} \mathrm{CuN}_{10} \mathrm{O}_{8}$ : calcd. C 38.35, H 3.22, N 20.33\%; found C 37.36, H 2.47, N 21.14\%. IR (KBr): v=3436, $1744,1732,1628,1561,1421,1369,1301,1253,1233,1020,761 \mathrm{~cm}^{-1} . \lambda_{\max }(\mathrm{MeOH}) 890$ $\mathrm{nm}, \varepsilon=110 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Magnetic moment: 2.12 B.M.

### 4.5.3.3 $\operatorname{Co}(4.4)_{2}(\mathrm{NCS})_{2}(4.14)$

$4.4(0.20 \mathrm{~g}, 0.65 \mathrm{mmol})$ was dissolved in $\mathrm{MeOH}(10 \mathrm{~mL}) . \mathrm{Co}(\mathrm{SCN})_{2}(0.11 \mathrm{~g}, 0.65 \mathrm{mmol})$ in $\mathrm{MeOH}(10 \mathrm{~mL})$ was added to the solution and the resulting purple solution was heated to reflux for 2 h . The solution was allowed to cool at room temperature and stood for several days until dryness. $\mathrm{MeOH}(5 \mathrm{~mL}$ ) was added to the residue and this solution was allowed to stand for 12 h , after which time a pink crystalline solid formed. This solid was filtered and washed with MeOH and dried. Crystalline pink solid ( 0.09 g, $38 \%$ ). $\mathrm{C}_{24} \mathrm{H}_{22} \mathrm{CoN}_{12} \mathrm{O}_{8} \mathrm{~S}_{2}$ : calcd. C 39.51, H 3.04, N 23.04\%; found C 40.29, H 3.03, N 22.37\%. IR (KBr): v = 3444,

## Chapter 5: Bis-Tetrazole Systems

### 5.1 Introduction

This chapter deals with the synthesis and employment of bis-tetrazole organic linkers in the formation of coordination polymers (CPs). The occurrence of bis-tetrazole CPs in the literature has increased enormously in recent years, with particular prominence in the last five years. This increased interest is due to a number of advantages; bis-tetrazole systems have abundant coordination sites with eight N atoms, which may be conducive to the diversity of networks, and with the development of solvothermal synthesis, the attainment of in situ generated tetrazole based CPs has attracted substantial interest, especially in cases where the novel CPs cannot be directly prepared from the ligands or by conventional methods.

Several bis-tetrazoles with various linkers joining the two heterocycles have been investigated. CPs employing 1,4-benzeneditetrazol-5-yl (BDT) (Figure 5.1) have been well documented in recent years. The earliest reported use of this linear ligand in terms of supramolecular architectures was by Molloy and co-workers in 2000. 225 However, it was the group of Dincǎ and Long in 2006 who identified that the carboxylate groups on a lot of commonly used bridging linkers at the time could be replaced by heterocyclic ligands, specifically tetrazoles or tetrazolates as in the case of BDT, with the result of forming analogous porous MOF structures exhibiting reversible $\mathrm{H}_{2}$ uptake with enhanced binding capabilities. ${ }^{155}$ This work demonstrated the utility of bis-tetrazole based ligands for producing robust MOFs with permanent porosity, and for possessing topologies and gas sorption characteristics mimicking those of carboxylate-based materials. In addition, with the discovery that tetrazoles gave rise to new structure types that had not yet been accessible using carboxylate chemistry and that changes in metal counteranion, solvent and reaction conditions influenced the topology and stability of the resulting frameworks, new opportunities became available to synthesise materials with drastically differing structures and properties. Accordingly, studies on BDT and its derivatives have steadily increased over the years. ${ }^{226}$

Figure 5.1: 1,4-benzeneditetrazol-5-yl (BDT).

One such derivative was developed by Jeong and colleagues, who synthesised and employed 2,6-di(1H-tetrazol-5-yl)naphthalene ( $\mathrm{H}_{2} \mathrm{NTD}$ ) (Figure 5.2), a ligand which contained a naphthyl group as a rigid linker connecting two tetrazole units. ${ }^{227}$ They reacted this ligand under solvothermal conditions with $\mathrm{MnCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}$ in DMF and MeOH at two different temperatures, resulting in two different MOFs due to the formation of trinuclear and pentanuclear SBUs. The free tetrazoles at the terminal ends of the naphthyl group provided a means of counterbalancing the charge on the metal centre, and this state of deprotonation with four possible donor nitrogen atoms offered diverse coordination modes and coordination chemistry.

Figure 5.2: Reacting $\mathrm{H}_{2} \mathrm{NTD}$ with $\mathrm{MnCl}_{2} .4 \mathrm{H}_{2} \mathrm{O}$ at different temperatures yielded two different MOFs with different topologies. 227

Examples of other rigidly linked bis-tetrazoles are prevalent in the literature and ligands belonging to this group are depicted in Figure 5.3.

Figure 5.3: A number of rigidly linked tetrazole ligands used to prepare CPs.

Bis-tetrazoles with more flexible linkers have also been examined for their ability to form coordination networks. Sun et al. synthesised bis-tetrazole methylene in situ from malononitrile with the aim of expanding the repertoire of tetrazole based MOFs. ${ }^{220}$ This ligand had abundant coordination sites with eight N atoms and in addition, the tetrazoles were separated by an alkyl " $\mathrm{CH}_{2}$ " spacer, which could add flexibility to the structure and endow the ligand with flexible bridging capabilities. Solvothermal reactions with $\mathrm{CdSO}_{4}$ and $\mathrm{ZnSO}_{4}$ and a secondary ligand, 2, 2'-bipyridine, produced 2-D networks where the ligands were adopting a bidentate chelating or bridging mode (Figure 5.4). The bidentate chelating mode was made possible by the proximity of the two tetrazole rings to each other. When the secondary ligand was changed to 4,4 '-bipyridine, a 3-D network was obtained (Figure 5.4), with the bis(tetrazole) methylene ligand retaining the bidentate chelating and bridging modes, but being further connected through pillars of 4,4'bipyridine to generate a 3-D architecture.

(b)

(c)

Figure 5.4: (a) Ball and stick plot showing coordination geometry around the Cd centres; (b) Perspective view of the 2-D networks, which in the case of the employment of 4,4'-bipy are joined by terminal bipy nitrogens; (c) Schematic representation of the topologies formed. ${ }^{220}$

Bis-tetrazole systems with increased flexibility between the tetrazole rings are rare. The paucity in examples of flexible tetrazole ligands can be attributed to the success of
conformationally rigid organic ligands yielding well defined coordination spheres. The use of geometrically fixed organic building blocks allows targeting of frameworks with certain topologies and such frameworks usually exhibit relatively high thermal and mechanical stability. In contrast to the prolific production of MOFs based on rigid ligands, the design, synthesis and applications of MOFs based on flexible ligands have so far not attracted as much attention. Indeed, increased flexibility makes it more difficult to forecast and control the final structures due to the ligands adopting different conformations, and crystallinity of the products can also be hampered. The structures of MOFs based on flexible ligands are more dependent on the various and subtle reaction parameters including temperature, time and pH . These factors severly hinder the development of knowledge and concepts that allow the rational design and prediction of extended network architectures with flexible organic ligands. Nonetheless, it presents an alluring challenge for supramolecular and materials chemists to harness the benefits of flexible ligands in a way that also produces crystalline predictable structures. These benefits include generating structural diversity that is inaccessible from rigid building blocks, generating homochiral MOFs due to the abundance of flexible chiral ligands (amino acids, peptides) and endowing the molecular architecture with a "breathing" ability and adaptive recognition properties. Wang and colleagues recognised the benefits of flexible organic linkers and improved their rigid tetrazole-based ligands ${ }^{228}$ by introducing flexible $\left(\mathrm{CH}_{2}\right)_{4}$ backbones, aiming to construct helix/loop subunits in polyoxometalates (POMs). ${ }^{229}$ POMs are a subset of metal oxides which usually consist of three or more transition metal oxyanions linked together by shared oxygen atoms to form a large closed 3-D framework. The transition metals are usually group 5 or 6 transition metals in their high oxidation states. POMs have recently been incorporated into the developing field of MOF chemistry, creating a new research field of POM-based MOFs. ${ }^{230}$ This is because they are highly regarded as being structurally outstanding SBUs due to their coordination ability, structural diversity and promising properties, such as catalytic activity, magnetism and electrochemical activities. ${ }^{229}$ Wang and co-workers suggested that flexible polydentate ligands may form the helix/loop subunits with ease owing to their flexibility and conformational freedom, which can make them conform to the coordination environment of the metal ions and POMs. ${ }^{229}$ The ligands synthesised are shown in Figure 5.5. They reported that the position of the N donor atom on the pyridine ring had an effect on the formation of helical subunits. The ligand with side N donors in the pyridyl group were conducive to forming helix/loop subunits, whereas terminal N donors led to dinuclear subunits (Figure 5.5). Furthermore, the influence of the flexible backbone was evident as the group stated that previously studied rigid precursors exclusively yielded isolated multinuclear units.

Helix/loop subunits

Figure 5.5: Schematic illustration of POM-based MOFs containing different Ag-ligand subunits. Diagram adapted and edited from Wang et al. ${ }^{229}$

Similar ligands (some of which are shown in Figure 5.6), albeit much simpler, have been employed in the synthesis of CPs whilst taking advantage of their flexibility. ${ }^{231,232}$ The use of bis-tetrazoles in these flexible systems is extremely limited, and the example presented by Wang et al. is indeed unique. ${ }^{229}$ This led us to question the applicability and usefulness of our tetrazole ligands in bis-systems, with both rigid and flexible backbones.

Figure 5.6: Flexible ligands with a $\left(\mathrm{CH}_{2}\right)_{\mathrm{n}}$ backbone have been employed in the synthesis of coordination polymers. Their occurrence is limited however, which may be partly due to the many polymorphs possible due to their conformational freedom.

### 5.2 Aims and Objectives of Chapter

In light of the above mentioned motivations, the goal of this chapter was to synthesise novel bis-tetrazole ligands and to investigate their potential to form multidimensional CPs. In our previous work, we successfully designed a series of pyridyl tetrazole ligands with a flexible tethered carboxylate group and introduced them into CP systems, and obtained novel networks and multinuclear clusters. In this work, we further developed these systems into bis-tetrazole systems, where the linkers introduced to join these moieties were varied. One approach was to introduce more flexibility into the precursors via introducing a flexible $\left(\mathrm{CH}_{2}\right)_{3}$ backbone with the aim of forming frameworks with potential voids. Unlike the ligands presented in Figures 5.5 and 5.6 , we aimed to synthesise pyridyl tetrazoles linked via this flexible backbone through the pyridine ring and not the tetrazole rings (Figure 5.7). These ligands would possess distinctive advantages in that they could provide multiple coordination sites by virtue of possessing pyridine and tetrazole N donors and carboxylate 0 donors; the carboxylate groups could allow for an expansion in dimensionality; and the relatively long spacer and the two pyridyl groups can rotate along its $\mathrm{C}-\mathrm{C}$ bonds to form nine main configurations, as observed in previous reports, thereby enabling the ligand to adopt versatile coordination modes and conformations (Figure 5.8).

Figure 5.7: The flexible bis-tetrazole systems that were intended to be synthesised in this work.

(b)

(c)

(d)

(e)

(f)

(g)

(h)

(i)

Figure 5.8: The main conformations of trimethylene linked heterocycles.

The second contrary approach was to connect two tetrazole rings by a more rigid linker; hence we aimed to make the ligands presented in Figure 5.9. These ligands would not have as much conformational freedom as the bptzap series, and would allow an investigation into the effect of spacer flexibility on CP structures. In addition, pyrazine nitrogens are well known for their donor capacities, therefore we expected coordination to the metal centres from this moiety would lead to higher dimensionality. The ligands would also possess tetrazole nitrogens and flexible carboxylate oxygen donor atoms, further increasing the probability of forming diverse structures with high dimensionality.

Figure 5.9: Bis-tetrazole ligands linked by a rigid pyrazine linker, which were synthesised as part of this work.

Therefore, the overall aims of this chapter were to synthesise novel bis-tetrazole ligands with different spacer groups. The bptzap series would possess a flexible $\left(\mathrm{CH}_{2}\right)_{3}$ backbone and the pzbtza series would include a rigid pyrazine spacer. These ligands would be produced with the aim of synthesising CPs with exciting topologies and properties for potential applications. The expected formation of regioisomers would also allow an assessment of how tetrazole substitution position would influence the final structures. We also aimed to gain higher dimensional CPs through using these ligands. Ultimately, we aimed to expand the area of rigid and flexible bis-tetrazole ligands in the realm of MOF chemistry and verify whether our improved strategy is rational for the construction of high dimensional materials. This may offer informative examples for the targeted syntheses of CPs. Importantly, to the best of our knowledge, research on these bistetrazole ligands in CPs have not been reported to date. Hence, this chapter represents a novel area of exploration.

### 5.3 Results and Discussion

### 5.3.1 Synthesis of Ligands

### 5.3.1.1 Synthesis of Bis-Tetrazole Ligands with Flexible $\left(\mathrm{CH}_{2}\right)_{3}$ Backbone

The synthesis of $5.1,5.2$ and 5.3 was achieved using a similar approach to that discussed in Chapter 4 (section 4.3.1.1). The synthetic route employed in this chapter is depicted in Scheme 5.1.

Scheme 5.1: Reagents and Conditions: i) $\mathrm{H}_{2} \mathrm{O}_{2}, \mathrm{CH}_{3} \mathrm{COOH}, 79^{\circ} \mathrm{C}, 20 \mathrm{~h}, 75 \%$; ii) DMCC,

\end{gathered}
$$

Access to these ligands was achieved by firstly oxidising commercially available 4,4'trimethylenebipyridine to the corresponding 1,3-bis(4-pyridyl)propane- $\mathrm{N}, \mathrm{N}$ '-dioxide (5.8). The formation of the N -oxide would activate the 2-position of the pyridine ring towards nucleophilic substitution by virtue of the electron resonance contributors discussed in section 4.3.1.1. Formation of the bis-N,N'-dioxide $\mathbf{5 . 8}$ was confirmed by the presence of a $v(\mathrm{~N}-\mathrm{O})$ frequency at $1230 \mathrm{~cm}^{-1}$ in the IR spectrum. The acquired data for 5.8 was consistent with that reported in the literature. ${ }^{233}$ The $\alpha$-cyanation of 5.8 has been reported once previously by Deng and colleagues, who employed TMSCN and benzoyl chloride to gain access to the bis-cyano derivative 5.9.232 Considering the success of our $\alpha$ cyanation method described in Chapter 4, we undertook $\alpha$-cyanation of 5.8 using the conditions of $\mathrm{Zn}(\mathrm{CN})_{2}$ and dimethylcarbamoyl chloride (DMCC) in toluene. However, problems were encountered due to the completely insoluble nature of 5.8 in toluene. Even when prolonged reaction times under reflux were employed, analysis by TLC revealed that no traces of product was formed at all, thus indicating that 5.8 was not dissolving even in trace amounts overtime. Hence, further modifications to this method were required.

Solubility testing showed that 5.8 was insoluble in many solvents. It did however dissolve in DMF over time, hence, the $\alpha$-cyanation of 5.8 was attempted in DMF under heated conditions. On work up of this reaction, a brown sticky residue was obtained. The ${ }^{1} \mathrm{H}$ NMR spectrum revealed that the residue contained a mixture of products, which when separated by flash column chromatography, yielded trace amounts of desired product and monosubstituted product. On probing the reason why this would have happened, the reactivity of the acyl chloride came into question. It was plausible for the very reactive acyl chloride to react with DMF, and on searching the literature, there were a number of examples of this incidence happening. ${ }^{234}$ On heating, DMF and DMCC can react to form $\mathrm{N}, \mathrm{N}, \mathrm{N}, \mathrm{N}^{\prime}$-tetramethylformamidinium chloride (Figure 5.10). Crude amidinium salts are notoriously intractable, being dark sticky oils, ${ }^{235}$ which correlated well with our observations. The crude ${ }^{1} \mathrm{H}$ NMR spectrum also alluded to the presence of this species, as methyl signals were observed at $\sim 3 \mathrm{ppm}$, and a singlet at 8.17 ppm was attributed to an imine proton. Hence, it was believed that the brown residue remaining on the column was this undesired product. No further pursuit of this product or its characterisation was carried out.

Figure 5.10: $\mathrm{N}, \mathrm{N}, \mathrm{N}^{\prime}, \mathrm{N}^{\prime}$-tetramethylformamidinium chloride.

Since formation of this product was tentatively proposed, prevention of this undesired reaction from occurring was attempted. The acylating agent, DMCC, was added slowly over one hour to a reaction mixture of $\mathrm{Zn}(\mathrm{CN})_{2}$ and 5.8 in DMF at $0^{\circ} \mathrm{C}$. The reaction was then allowed to slowly warm up to room temperature overnight. After work up and extraction with DCM, the crude mixture was again analysed by ${ }^{1} \mathrm{H}$ NMR spectroscopy. Methyl peaks and a singlet at 8.17 ppm were again visible in the spectrum, however the presence of three aromatic signals was also observed, indicating successful substitution of the pyridine ring. A comparison of the relative integrations for the peaks indicated that formation of the amidinium side product was somewhat alleviated. The mixture was passed through a silica plug using EtOAc and Pet. Ether as the eluent in a $3: 1$ ratio. This yielded a white crystalline solid with isolated yields of around $30 \%$. As well as the ${ }^{1} \mathrm{H}$ NMR spectrum displaying three aromatic signals, there was further evidence that a nitrile group was present at the 2-position of the pyridine ring. In the IR spectrum of 5.9, a sharp peak was
positioned at $2237 \mathrm{~cm}^{-1}$, which was attributed to the $v(\mathrm{C} \equiv \mathrm{N})$ vibrational mode. In the ${ }^{13} \mathrm{C}$ NMR spectrum, a peak concomitant with a nitrile carbon was observed at 117.2 ppm . To address the poor yields obtained in this reaction, several attempts at optimisation were carried out. Longer reaction times resulted in no increase in yields. Employing a different acylating agent, benzoyl chloride, also resulted in a side reaction with DMF. Different solvents were also utilised, but in all cases, no product was observed. DMF was the only solvent capable of dissolving both $\mathrm{Zn}(\mathrm{CN})_{2}$ and $\mathbf{5 . 8}$ in sufficient quantities to react. Although these yields were not ideal, no further optimisation was carried out at this point. The collated data acquired for $\mathbf{5 . 9}$ was consistent with that reported by Deng et al. ${ }^{232}$ Synthesis of the ligands continued with a 1,3-dipolar cycloaddition using conditions described previously (section 2.3.1). The product, 5.10, was analysed by NMR and IR spectroscopies and HRMS. The IR spectrum of $\mathbf{5 . 1 0}$ displayed a broad stretch at $\sim 3386$ $\mathrm{cm}^{-1}$ which was indicative of the $v(\mathrm{~N}-\mathrm{H})$ vibrational mode of the protonated tetrazole. Additional stretching frequencies in the region $1562-1633 \mathrm{~cm}^{-1}$ indicated the presence of tetrazole rings. Furthermore, the $v(\mathrm{C} \equiv \mathrm{N})$ frequency was absent which was anticipated if it had been consumed during the reaction. The presence of two tetrazole rings was also indicated by the ${ }^{1} \mathrm{H}$ NMR spectrum which exhibited five resonances: three aromatic signals and two alkyl chain resonances attributed to the propyl chain protons. This implied a symmetrical system and therefore indicated bis-substitution. The tetrazole quaternary C-5 peak was positioned at 154.9 ppm in the ${ }^{13} \mathrm{C}$ NMR spectrum, which is typical of C-5 resonances of protonated tetrazole rings. Finally, HRMS analysis revealed the presence of a molecular ion peak at $\mathrm{m} / \mathrm{z} 335.1476$ which corresponded to $(\mathbf{5 . 1 0 +}+)^{+}$with an error of -0.03 ppm . Thus, the data acquired for $\mathbf{5 . 1 0}$ supported the presence of two tetrazole rings being present. Alkylation of $\mathbf{5 . 1 0}$ was then carried out in the presence of base, using ethyl bromoacetate. On analysis of the crude residue by ${ }^{1} \mathrm{H}$ NMR spectroscopy, the spectrum initially appeared complicated. However, it could be deduced that there were three products present in the mixture, most plausibly the $\mathrm{N}-1, \mathrm{~N}-1^{\prime} ; \mathrm{N}-2, \mathrm{~N}-2^{\prime}$ and $\mathrm{N}-1, \mathrm{~N}-2^{\prime}$ substituted regioisomers. The crude mixture was separated by flash column chromatography using a gradient system. This was necessary to obtain the products with low $R_{f}$ values in a clean, well separated manner. On first attempt, traces of a fourth monosubstituted product was also produced, however in very small quantities. This was alleviated by using more equivalents of $\mathrm{K}_{2} \mathrm{CO}_{3}$ and ethyl bromoacetate. The separated fractions were analysed by NMR spectroscopy and the ${ }^{13} \mathrm{C}$ NMR spectra of the compounds revealed the substitution on the tetrazole rings. The first product to elute was the $\mathrm{N}-1, \mathrm{~N}-1$ ' regioisomer 5.1, as indicated by the single C-5 resonance peak at 152.2 ppm . The second product to elute was the $\mathrm{N}-1, \mathrm{~N}-\mathbf{2}^{\prime}$ regioisomer 5.2 as indicated by the additional ${ }^{13} \mathrm{C}$
resonances present which supported the presence of asymmetry in the molecule. The ${ }^{1} \mathrm{H}$ NMR spectrum also clearly showed that this was the case (Figure 5.11). The ${ }^{13} \mathrm{C}$ NMR spectrum exhibited a C-5 resonance at 164.1 ppm for the $\mathrm{N}-2$ substituted ring and at 151.4 ppm for the $\mathrm{N}-1$ substituted ring. The ${ }^{1} \mathrm{H}$ NMR spectrum showed the same trends as seen in previous alkylated tetrazoles, with the $\mathrm{N}-1$ methylene group being more deshielded in the $\mathrm{N}-1$ substituted tetrazoles than the $\mathrm{N}-2$ substituted tetrazole rings. The final product that eluted was the $\mathrm{N}-2, \mathrm{~N}-2$ ' regioisomer 5.3 which was confirmed by ${ }^{13} \mathrm{C}$ NMR spectroscopy where the single C-5 resonance for the tetrazole ring resonated at 164.8 ppm.

Figure 5.11: ${ }^{1} \mathrm{H}$ NMR spectra, obtained in $\mathrm{CDCl}_{3}$, of $\mathbf{5 . 1}$ (blue), $\mathbf{5 . 2}$ (green) and $\mathbf{5 . 3}$ (red). Relevant signals are labelled for 5.1.

Single crystals of 5.1 were grown and analysed by X-ray crystallography (Figure 5.12). 5.1 crystallises with the ester groups being almost orthogonal with respect to the plane of the tetrazole rings $\left(66(1)^{\circ}\right)$. This observation is similar to that seen in other $\mathrm{N}-1$ ester functionalised tetrazoles that were synthesised previously in this thesis. There is also a notable bend in the molecule; the propyl chain is in the same plane as one pyridyl tetrazole unit, with the other pyridyl tetrazole being nearly perpendicular to this plane. There are no intermolecular hydrogen bonds present in the packing diagram.

Figure 5.12: View of the molecular structure of 5.1, and view of conformational bend in the molecule.

### 5.3.1.2 Synthesis of Bis-Tetrazole Ligands with Rigid Pyrazine Backbone

The synthesis of ligands $5.4,5.5$ and 5.6 was achieved by the synthetic route shown in Scheme 5.2. 2,3-di(1H-tetrazol-5-yl)pyrazine (5.12) was synthesised from the 2,3pyrazinedicarbonitrile precursor in $67 \%$ yield as an orange crystalline solid. The acquired data for $\mathbf{5 . 1 2}$ correlated well with literature values.120,156

(ii) 5.12

5.4

5.5

Scheme 5.2: Synthetic scheme for the synthesis of 5.4, 5.5 and 5.6. Reagents and conditions: i) $\mathrm{NaN}_{3}, \mathrm{NH}_{4} \mathrm{Cl}, \mathrm{LiCl}, \mathrm{DMF}, 110^{\circ} \mathrm{C}, 12 \mathrm{~h}, 67 \%$; ii) DIEA, $\mathrm{BrCH}_{2} \mathrm{COOEt}, \mathrm{MeCN}, 82$ ${ }^{\circ} \mathrm{C}, 24 \mathrm{~h}, 23 \%(5.4), 10 \%(5.5), 9 \%(5.6)$.

The McGinley group has previously achieved alkylation of 5.12 employing $\mathrm{Et}_{3} \mathrm{~N}^{120}$ Utilising these conditions for our purposes did lead to alkylation, however it also unsurprisingly hydrolysed the ester groups and there was concern over the feasibility of separating carboxylic acid derivatives by column chromatography if it was required. $\mathrm{N}, \mathrm{N}$ Diisopropylethylamine (DIEA) was therefore employed instead, as it is an organic base which is non-nucleophilic. This is due to the steric bulk of the isopropyl and ethyl groups which allow only a proton to be abstracted from a substrate. ${ }^{236}$ Thus, $\mathbf{5 . 1 2}$ was reacted with DIEA and ethyl bromoacetate in MeCN at reflux temperature for 24 h . The resulting orange clear solution was reduced in vacuo and washed with $\mathrm{H}_{2} \mathrm{O}$ in order to remove excess DIEA. TLC analysis of the crude mixture revealed three spots which were overlapping, and the crude ${ }^{1} \mathrm{H}$ NMR spectrum also indicated the presence of three products. Several combinations of TLC solvent systems were investigated, however clear separation of the spots remained unattainable. On attempting to purify the residue by column chromatography using the best solvent system observed by TLC, the spots eluted at the same time, therefore separation of the regioisomers had to be achieved by other means. In hypothesising that the regioisomers' solubilities might be sufficiently different from each other, slow precipitation of the products was attempted in many solvents. It was found that a mixture of MeOH , Pet. Ether and $\mathrm{CHCl}_{3}$ produced a crystalline solid, which was filtered and dried. ${ }^{1} \mathrm{H}$ NMR spectroscopy alluded to the asymmetric nature of this solid (5.4) as all signals were split due to this asymmetry (Figure 5.13). The ${ }^{13} \mathrm{C}$ NMR spectrum also had many resonances present, with the tetrazole C-5 carbons resonating at 162.1 ppm for the $\mathrm{N}-2$ substituted tetrazole and 150.8 ppm for the $\mathrm{N}-1$ substituted tetrazole. Asymmetry was also confirmed by IR spectroscopy as two $v(\mathrm{C}=0)$ vibrational modes were positioned at 1745 and $1757 \mathrm{~cm}^{-1}$. On sitting the filtrate for a further day, another crop of white solid formed (5.5) which when analysed by ${ }^{1} \mathrm{H}$ NMR spectroscopy proved to be a symmetrically substituted compound, which was evident by the ${ }^{1} \mathrm{H}$ NMR spectrum obtained (Figure 5.13). The position of the alkyl ester on the tetrazole ring was elucidated by analysing the ${ }^{13} \mathrm{C}$ NMR spectrum for $\mathbf{5 . 5}$, which had a peak at 150.5 ppm that indicated that 5.5 was the $\mathrm{N}-1, \mathrm{~N}-1^{\prime}$ substituted isomer. The IR spectrum also had a single $v(\mathrm{C}=0)$ stretch at $1750 \mathrm{~cm}^{-1}$. Isolation of the remaining $\mathrm{N}-2, \mathrm{~N}-2^{\prime}$ isomer proved difficult. This isomer always remained in the filtrate and therefore was in the presence of other impurities as well as traces of $\mathbf{5 . 4}$ and 5.5. Therefore as it crystallised out of solution, it was often along with these impurities. After several recrystallisations of this regioisomer however, clean product (5.6) was eventually obtained. Prolonged periods of time in the presence of MeOH did occasionally result in transesterification to the methyl ester
derivatives. The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{5 . 6}$ is represented by the blue spectrum in Figure 5.13. The symmetrical nature of the molecule was immediately obvious, as a singlet integrating for two protons which was associated with the pyrazine protons was observed. A single singlet attributed to the methylene group bonded to the tetrazole ring was also present, as was a quartet integrating for four protons and a triplet integrating for six protons which were attributed to the ethoxy protons. The $\mathrm{N}-2$ substituted nature of the tetrazole rings was confirmed by ${ }^{13} \mathrm{C}$ NMR spectroscopy where the anticipated C-5 of the tetrazole ring was positioned at 162.6 ppm . The IR spectrum of 5.6 was similar to 5.5 with a single $v(\mathrm{C}=0)$ vibrational mode positioned at $1745 \mathrm{~cm}^{-1}$.

Figure 5.13: ${ }^{1} \mathrm{H}$ NMR spectra of crude mixture (black), $\mathbf{5 . 4}$ (red), $\mathbf{5 . 5}$ (green) and $\mathbf{5 . 6}$ (blue) which were carried out in $\mathrm{CDCl}_{3}$ (with some $\mathrm{H}_{2} \mathrm{O}$ present at 1.56 ppm ).

Single crystals of $\mathbf{5 . 4}$ and 5.5 were analysed by X-ray crystallography and the results of this analysis can be seen in Figures 5.14 and 5.15. In 5.4, neither of the tetrazole rings are co-planar with the pyrazine ring, with the $\mathrm{N}-1$ substituted tetrazole ring being especially twisted with respect to the pyrazine ring (forms a dihedral angle of 69.5(3) ${ }^{\circ}$ compared to $7.3(3)^{\circ}$ for $\mathrm{N}-2$ the tetrazole ring). We can conclude from this observation that the position of the substituent in the $\mathrm{N}-1$ substituted tetrazole is greatly hindering the existence of coplanar systems.

Figure 5.14: Crystal structure of 5.4 viewed from two perspectives. Figure on right has hydrogen atoms omitted for clarity.

The crystal structure of $\mathbf{5 . 5}$ can be seen in Figure 5.15. In comparison to the crystal structure for 5.4, 5.5 shows considerable puckering between both tetrazole rings and the pyrazine ring, with the plane of the pyrazine ring and the tetrazole rings forming a dihedral angle of $35.4(6)^{\circ}$ for the N 12 substituted ring and $30.1(6)^{\circ}$ for the N22 substituted ring. Again, it can be deduced that the substitution at the $\mathrm{N}-1$ position of the tetrazole ring causes a significant amount of steric hindrance in these type of systems, so much so that even puckering of the pyrazine ring is observed in the crystal structure.

Figure 5.15: (a) Crystal structure of 5.5 viewed along the $a$-axis, (b) structure viewed with pyrazine pointing back into the page, highlighting the distortion of the tetrazole rings from the plane of the pyrazine ring. Hydrogen atoms are omitted for clarity.

### 5.3.2 Metal Complexation Reactions

### 5.3.2.1 Metal Complexation Reactions with Flexible Bis-Tetrazole Ligands

Reactions of $\mathbf{5 . 1}$ with $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}, \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}, \mathrm{Cu}(\mathrm{OAc})_{2}$ in MeOH resulted in the attainment of unreacted ligand. Reaction of $\mathbf{5 . 1}$ with $\mathrm{CuCl}_{2} 2 \mathrm{H}_{2} \mathrm{O}$ in EtOH however did yield a green precipitate. This solid (5.13) was filtered, dried and analysed by IR spectroscopy, elemental analysis and magnetic moment measurements. Room temperature magnetic moment measurements yielded a $\mu_{\text {eff }}$ value of 1.9 B.M which was a typical value of a $\mathrm{d}^{9}$ metal ion. The IR spectrum of $\mathbf{5 . 1 3}$ displayed frequency shifts when compared to the starting ligand 5.1. Complexation to the ester moiety was not alluded to as there were no significant shifts observed for the $v(\mathrm{C}=0)$ vibration. Complexation to the pyridine and tetrazole moieties was suggested as shifts in the heterocyclic frequencies were observed. Elemental analysis alluded to a $1: 1$ metal to ligand composition. The material was very insoluble which led us to believe that the material was polymeric. A structure was proposed which can be seen in Figure 5.16. It was proposed that the $\mathrm{Cu}(\mathrm{II})$ ion was in an octahedral environment, coordinated by two pyridine and tetrazole $\mathrm{N}-1$ nitrogens and two chloride anions. The $\mathrm{Cu}(\mathrm{II})$ ion was proposed to connect two different ligands, propagating a 1-D coordination polymer.

Figure 5.16: Proposed structure of a subunit of coordination polymer 5.13.

Reacting 5.2 with $\mathrm{CuCl}_{2} 2 \mathrm{H}_{2} \mathrm{O}$ in EtOH resulted in a dark green precipitate forming in solution. The solid was analysed by IR spectroscopy and compared to that of the starting material. The $v(\mathrm{C}=0)$ vibrational mode had shifted to a lower wavenumber and was now positioned at $1743 \mathrm{~cm}^{-1}$, which indicated that no complexation was occurring to the ester moiety but that complexation to the ligand had occurred. Shifts in the heterocyclic stretches were observed which indicated that there were interactions with the heterocyclic nitrogens and the metal atom. Elemental analysis suggested that the solid had a 2:1 metal to ligand ratio. The solid was insoluble in most solvents, so it was proposed that the material was polymeric. With this in mind, a structure was tentatively assigned to
the solid and this structure can be seen in Figure 5.17. The structure consists of dichlorobridged subunits with each $\mathrm{Cu}(\mathrm{II})$ centre possessing a square pyramidal geometry. The polymeric chain propagates through coordination of another subunit to the coordinatively unsaturated $\mathrm{Cu}(\mathrm{II})$ centre shown in Figure 5.17. Elemental analysis correlated well with the calculated values for this structure, and chloride bridging has been observed before in pyridyl tetrazole complexes synthesised in this thesis (Chapter 2 and 3).

Figure 5.17: Proposed structure of 5.14 , which could be a subunit of a polymeric chain.

On reacting in situ generated dicarboxylates $\mathbf{5 . 1}$ (bptzap), $\mathbf{5 . 2 ( b p t z a p )}$ and $\mathbf{5 . 3 ( b p t z a p )}$ with metal salts, insoluble powders formed from the solution. IR spectroscopy, elemental analysis and magnetic moment analysis was carried out on these products, however, definitive structures could not be suggested. This was due to the many conformations that the ligands could adopt. It was reasonable to assume coordination to the carboxylate oxygens and the pyridyl tetrazole nitrogens as IR analysis suggested that this was the case. The attainment of single crystals was attempted by changing reaction parameters however, the formation of an amorphous powder was not avoided. The use of solvothermal techniques has proved to be a useful technique in order to obtain crystalline products. This method will be pursued in future work as a means to obtain single crystals and characterise the structures formed by the flexible bptzap series.

### 5.3.2.2 Metal Complexation Reactions with Rigid Pyrazine Ligands

5.4 was nonsolvothermally converted to $\mathbf{5 . 4}$ (pzbtza) in situ using aqueous NaOH . After heating this solution for two hours, $\mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ was added to the solution and the resulting blue solution was cooled slowly and allowed to stand for several days. Block shaped royal blue crystals formed after this time which were filtered and dried. The IR spectrum of the blue solid $\mathbf{5 . 1 5}$ revealed that no protonated carboxylic acid was present in the structure. Monodentate coordination to $\mathrm{Cu}(\mathrm{II})$ was suggested as a $\mathrm{v}_{\text {asym }}\left(\mathrm{COO}^{-}\right)$vibration was observed at $1660 \mathrm{~cm}^{-1}$ and the corresponding $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$was positioned at $1377 \mathrm{~cm}^{-1}$,
yielding a $\Delta\left(v_{\text {asym }}\left(\mathrm{COO}^{-}\right)-v_{\text {sym }}\left(\mathrm{COO}^{-}\right)\right)$value of $283 \mathrm{~cm}^{-1}$. A broad strong stretch was positioned at $3419 \mathrm{~cm}^{-1}$ which indicated coordinating $\mathrm{H}_{2} \mathrm{O}$ molecules and possible hydrogen bonding. The presence of $\mathrm{H}_{2} \mathrm{O}$ was also alluded to in elemental analysis studies. The single crystals obtained were analysed by X-ray crystallography and the results proved to be quite interesting (Figure 5.18). $\mathbf{5 . 1 5}$ crystallises as a 2-D coordination polymer which extends along the $a$ - and $b$-axis. These sheets are further connected into a 3-D hydrogen bonded network. There are two crystallographically unique $\mathrm{Cu}(\mathrm{II})$ cations in the asymmetric unit. Each $\mathrm{Cu}(\mathrm{II})$ centre possesses a distorted square pyramidal geometry. It is coordinated to one $\mathrm{H}_{2} \mathrm{O}$ molecule, two tetrazole nitrogens from the same ligand but different rings and two carboxylate oxygens from two different ligands coordinating in a monodentate fashion. Two nitrogen atoms (N22A, N12A for Cu1; N22B, N12B for Cu2) and two oxygens (01A, 03A for Cu1; 01B, 03B for Cu2) form the base of the pyramid and one $\mathrm{H}_{2} \mathrm{O}$ molecule ( 01 W for Cu 1 and 02 W for Cu 2 ) occupies the apical position. Each ligand therefore is coordinated to three $\mathrm{Cu}(\mathrm{II})$ atoms via their $\mathrm{N}-1$ nitrogens of the tetrazole rings and its two carboxylate oxygens. This correlated well with the observations seen in the IR spectrum of 5.15. There was no coordination observed to the pyrazine and tetrazole nitrogens to form a chelate ring, which was somewhat surprising. However, this could be plausibly explained by the sterics of the system. When compared to the crystal structure of the ligand 5.4, the coordination of $\mathrm{Cu}(\mathrm{II})$ has the effect of puckering both tetrazole rings. Therefore the $\mathrm{N}-1$ substituted tetrazole is now less twisted with respect to the pyrazine ring and the $\mathrm{N}-2$ substituted tetrazole is now more twisted with respect to the pyrazine ring when compared to free ligand 5.4. However, the $\mathrm{N}-1$ substituted ring is still more twisted relative to the $\mathrm{N}-2$ substituted ring (torsion angles of $43.7(6)^{\circ}$ and $-40.7(6)^{\circ}$ for N 2; $-47.7(6)^{\circ}$ and $50.2(6)^{\circ}$ for $\mathrm{N}-1$ ). The seven membered chelate ring formed is puckered due to this twisting. A fascinating structural feature of $\mathbf{5 . 1 5}$ are the clusters of acyclic hexanuclear $\mathrm{H}_{2} \mathrm{O}$ molecules that are present in the asymmetric unit (Figure 5.19).
(a)

(b)

Figure 5.18: (a) Subunit of 5.15, uncoordinated $\mathrm{H}_{2} \mathrm{O}$ molecules omitted for clarity; (b) 2-D MOF with potential voids occupied by uncoordinated $\mathrm{H}_{2} \mathrm{O}$ molecules.

Figure 5.19: Hexameric $\mathrm{H}_{2} \mathrm{O}$ cluster that is present in the asymmetric unit of $\mathbf{5 . 1 5}$ (top) and 1-D $\mathrm{H}_{2} \mathrm{O}$ chain viewed along the $b$-axis (bottom).

01 W acts as both a hydrogen bond acceptor and donor, 02W acts as a double hydrogen bond donor (both 01 W and 02 W are also coordinated to Cu 1 and Cu 2 respectively), 03 W and 04 W acts as a double hydrogen bond donor and double hydrogen bond acceptor and 05 W and 06W acts as a double hydrogen bond donor and acceptor. The $0 \cdots 0$ distances in the hexanuclear cluster fall in the range of $2.709(6)-2.833(6) \AA$ with an average value of $2.763 \AA$, compared with $2.76 \AA\left(-90^{\circ} \mathrm{C}\right)$ in hexagonal ice or $2.74 \AA$ in cubic ice. $237,238,239$ This cluster is also stabilised in the network through $\mathrm{O}_{\text {water }}-\mathrm{H} \cdots \mathrm{O}_{\text {carboxyl }}$ hydrogen bonds. Throughout the 2-D coordination sheet, four crystallographically independent $\mathrm{H}_{2} \mathrm{O}$ molecules (01W, 02W, 03W, 04W) are hydrogen bonded to each other forming an infinite
$\mathrm{H}_{2} \mathrm{O}$ chain with a curl conformation (Figure 5.19). The arrangement mode of the $\mathrm{H}_{2} \mathrm{O}$ molecules within the chain can be described as $\cdots 02 \mathrm{~W} \cdots 03 \mathrm{~W} \cdots 01 \mathrm{~W} \cdots 04 \mathrm{~W} \cdots$. The overall $\left[\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]_{\mathrm{n}}$ chain can be represented by C4, according to the $\mathrm{H}_{2} \mathrm{O}$ cluster nomenclature described by Infantes and co-workers. ${ }^{240,241}$ The literature relating to the structure of pure $\mathrm{H}_{2} \mathrm{O}$ in both the solid and liquid state as well as in mixed-component systems, is extensive. ${ }^{238}$ An improved understanding of the three-dimensional structural aspects of $\mathrm{H}_{2} \mathrm{O}$ has important implications in the area of structural biology. Several examples have demonstrated the importance of $\mathrm{H}_{2} \mathrm{O}$ structuring, including the structures of Scapharca dimeric haemoglobin, ${ }^{242}$ actinidin ${ }^{243}$ and carbonic anhydrase C. ${ }^{244}$ There is much evidence that alludes to the presence of ordered $\mathrm{H}_{2} \mathrm{O}$ clusters in the active clefts of these proteins, but unambiguous positional information is still rare. It is thought that $\mathrm{H}_{2} \mathrm{O}$ molecules contribute to the complex stability by mediating hydrogen bonds between functional groups of the protein and the ligands, and by filling potential voids or holes inside the binding site. ${ }^{245}$ Given the influence of $\mathrm{H}_{2} \mathrm{O}$ on the structure and function of biological systems and its fundamental role in almost all branches of natural sciences it is not surprising that hydrogen bonded $\mathrm{H}_{2} \mathrm{O}$ aggregates have received much attention. Accurate structural data of low dimensional $\mathrm{H}_{2} \mathrm{O}$ structures is key in the elucidation of the complex interplay of biological, chemical and structural properties of $\mathrm{H}_{2} \mathrm{O}$, which is surprisingly still not fully understood. Coordination compounds, MOF structures, and suitable organic compounds can provide ideal void spaces to trap fractions of ice or other hydrogen bonded $\mathrm{H}_{2} \mathrm{O}$ aggregates and these have been utilised to simulate $\mathrm{H}_{2} \mathrm{O}$ crystallisation in restricted environments. ${ }^{246}$ Over the years, such structures have been characterised and categorised; ${ }^{240}$ examples include defined oligomeric $\mathrm{H}_{2} \mathrm{O}$ aggregates $\left(\mathrm{H}_{2} \mathrm{O}\right)_{\mathrm{n}}$ ( $\mathrm{n}=2$ 100),,239,247 1-D chains or tapes ${ }^{248}$ and 2-D layered structures. ${ }^{249}$ The precise structural data and the cooperative association of the water cluster and crystal host in $\mathbf{5 . 1 5}$ may be helpful in improving our understanding of the contribution of water clusters to the stability and function of biological assemblies, as well as the anomalous properties of water.

Reaction of $\mathbf{5 . 5}$ (pzbtza) and $\mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ in aqueous NaOH resulted in the formation of pale blue block-like crystals on standing for 1 day. The crystals were analysed by IR spectroscopy, elemental analysis and X-ray crystallography. The IR spectrum of $\mathbf{5 . 1 6}$ indicated that there was no protonated carboxylate present. The presence of a $v_{\text {asym }}\left(\mathrm{COO}^{-}\right)$ vibration at $1640 \mathrm{~cm}^{-1}$ with a corresponding $v_{\text {sym }}\left(\mathrm{COO}^{-}\right)$vibration positioned at $1380 \mathrm{~cm}^{-1}$ suggested that the deprotonated carboxylates were adopting a monodentate coordination to the metal centre. A broad stretch at $3050 \mathrm{~cm}^{-1}$ alluded to the presence of $\mathrm{H}_{2} \mathrm{O}$ in the
structure. Elemental analysis suggested a 1:1 metal to ligand ratio. The crystal structure of 5.16 reveals mononuclear subunits, with the $\mathrm{Cu}(\mathrm{II})$ ion in an axially distorted octahedral environment. Bond lengths between the $\mathrm{Cu}(\mathrm{II})$ ion and the axial water molecules are 2.32 and $2.56 \AA$ for 01 W and 02 W , respectively. These lengths are in contrast to the equatorially coordinated ligands, with bond lengths of $\sim 2.00 \AA$ being observed. The equatorial plane of the octahedron is occupied by two tetrazole $\mathrm{N}-1$ nitrogens from the same ligand, two carboxylate oxygens from two different ligands adopting a monodentate binding mode and two $\mathrm{H}_{2} \mathrm{O}$ molecules which occupy the axial positions. The bonding arrangement leads to a 2-D coordination polymer, with each ligand bonded to three $\mathrm{Cu}(\mathrm{II})$ atoms (Figure 5.20).
(a)

(c)

Figure 5.20: (a) Repeating unit of coordination polymer 5.16 viewed along the $b$-axis, hydrogen atoms omitted for clarity; (b) subsection of 5.16 viewed along $b$-axis; (c) view of propagation in $\mathbf{5 . 1 6}$ viewed along $c$-axis.

Each asymmetric unit extends in two directions forming a 2-D coordination layer, propagating along the crystallographic $a$ - and $c$-axes. Despite the presence of coordinated $\mathrm{H}_{2} \mathrm{O}$ molecules, there are no hydrogen bonds observed between the sheets, and no other significant interactions are present. Hydrogen bonding does exist between 02 and 01W and between 01 and 02W on the same 2-D sheet however. To describe the topology of 5.16, the underlying net can be termed as having a 4 -connected topology with the Cu (II) centre acting as a 4 -coordinated node. This mode of bonding is schematically represented in Figure 5.21 . The space surrounded by these nodes are filled by the pyrazine ring, however we believe that extending the length of the linker between the tetrazole ring and carboxyl group could expand these pores.

(b)

(d)

Figure 5.21: (a) Packing diagram viewed along $c$-axis showing 2-D sheets stacked on top of one another; (b) packing diagram viewed along $a$-axis, no interactions occur between the sheets; (c) perspective view of the 2-D network of $\mathbf{5 . 1 6}$ and (d) simplified schematic of 2-D topology of 5.16. Pyrazine ring was omitted for clarity in (c) and (d).

### 5.3.3 EPR Studies

The X-band EPR spectra of $\mathbf{5 . 1 5}$ was measured in the solid state as a powder at room temperature. Figure 5.22 displays the EPR spectrum of 5.15 , which resembles an isotropic signal, where $g_{\mathrm{x}}=g_{\mathrm{y}}=g_{\mathrm{z}}$. It was thought that this signal could have been overlapping with another signal, however it was proposed that the crystallinity of the sample could perturb the signal (samples were ground however crystalline particles always remained). The extracted $g$ factor (2.191) was typical of a transition metal unpaired electron as it was much greater than the free electron $g_{\mathrm{e}}$ value. ${ }^{176}$ An isotropic signal implies that the three principle axes are the same and on examination of the bond distances around the $\mathrm{Cu}(\mathrm{II})$ centres (which are all $\sim 2 \AA$ ) this was observed to be in agreement with the crystal structure obtained.

Figure 5.22: Room temperature 9.63 GHz EPR spectrum of a powder sample of 5.15. $g_{\mathrm{x}}=$ $g_{\mathrm{y}}=g_{\mathrm{z}}=2.19$.

### 5.4 Conclusions

In previous chapters, carboxylate functionalised pyridyl tetrazoles were employed in the synthesis of CPs with the result of forming 1-D CPs or isolated bimetallic units. The work outlined in this chapter aimed to increase the dimensionality of these polymers by utilising carboxylate functionalised bis-tetrazole systems. Furthermore, the bis-tetrazole ligands were linked via a rigid pyrazine ring or a flexible propyl chain backbone, allowing an examination of how flexibility of the backbone affects the final structures. Higher dimensionality was successfully achieved with 2-D coordination polymers being formed when the pyrazine bis-tetrazole systems were employed. The 2-D coordination polymer based on the asymmetric substituted pyrazine bis-tetrazole was further connected into a 3-D coordination network through hydrogen bonding between $\mathrm{H}_{2} \mathrm{O}$ molecules. These $\mathrm{H}_{2} \mathrm{O}$ molecules were connected as a 1-D chain thoughout the structure. $\mathrm{H}_{2} \mathrm{O}$ aggregates in crystal hosts are gaining a lot of interest in recent years as they provide diverse environments in which to obtain precise structural information about the bonding properties of $\mathrm{H}_{2} \mathrm{O}$.

Elucidation of the CPs formed in experiments utilising trimethylene linked pyridyl tetrazoles proved difficult. Crystalline samples were difficult to obtain which hampered elucidation of the structures by X-ray crystallography. Despite microwave synthesis yielding similar results, we maintain that the use of alternative synthesis methods could alleviate these issues and yield crystalline products. Hence, future efforts will include the use of solvothermal synthesis. Although dramatic advancement has been made, research into CPs based on flexible ligands is still at an early stage of development. As previously stated, flexible ligands themselves can adopt different conformations with distinct
symmetries as a consequence of rotations around single bonds during the self-assembly process, which greatly deters the ability to design and predict the form of extended network architectures. As the synthesis conditions such as reaction temperature, solvents, counteranions, organic templates, pH etc. can influence the conformations of flexible ligands and therefore the final structures, a high degree of predictability must be integrated prior to synthesis. Further research efforts are indispensable to fully understand the structural features and the structure-property relationship in framework materials, in order to establish reliable strategies for the design and synthesis of targeted flexible based CPs.

Further future work involves incorporating higher dimensionality into the frameworks thereby forming 3-D frameworks which would possess potential voids. One possible way this could be achieved is through the use of a mixed linker approach which has been proven to be successful in obtaining porous frameworks. Hence, we intend on adding 4,4'bipyridine as it is an excellent bridging ligand and could be capable of connecting the 2-D coordination sheets synthesised in this chapter via coordination to two $\mathrm{Cu}(\mathrm{II})$ atoms on two separate sheets. In addition, elongation of the linkages between the carboxylate and tetrazole ring will be carried out with the aim of extending the pore sizes in the frameworks.

### 5.5 Experimental

### 5.5.1 Instrumentation

${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR ( $\delta \mathrm{ppm} ; J \mathrm{~Hz}$ ) spectra were recorded on a Bruker Avance 300 MHz NMR spectrometer using saturated $\mathrm{CDCl}_{3}$ or $d_{6}$-DMSO solutions with a $\mathrm{SiMe}_{4}$ reference, with resolutions of 0.18 Hz and 0.01 ppm , respectively. Infrared spectra ( $\mathrm{cm}^{-1}$ ) were recorded as KBr discs or liquid films between NaCl plates using a Perkin Elmer System 2000 FT-IR spectrometer. Solution UV-Vis spectra were recorded using HPLC grade solvents using a Unicam UV 540 spectrometer. Melting point analyses were carried out using a Stewart Scientific SMP 1 melting point apparatus and are uncorrected. Electrospray (ESI) mass spectra were collected on an Agilent Technologies 6410 Time of Flight LC/MS. Compounds were dissolved in acetonitrile:water (1:1) solutions containing $0.1 \%$ formic acid, unless otherwise stated. The interpretation of mass spectra was made with the help of the program "Agilent Masshunter Workstation Software". Magnetic susceptibility measurements were carried out at room temperature using a Johnson Matthey Magnetic Susceptibility Balance with $\left[\mathrm{HgCo}(\mathrm{SCN})_{4}\right]$ as reference. EPR spectra were recorded on a Bruker Elexsys E500 spectrometer, operated at the X-band and equipped with an Oxford Instruments cryostat. Microanalyses were carried out at the Microanalytical Laboratory of the National University of Ireland Maynooth, using a Thermo Finnigan Elementary Analyzer Flash EA 1112. The results were analysed using Eager 300 software. All crystal structures resulting from this work were solved by Dr. John Gallagher (Dublin City University) using an Oxford Diffraction Gemini-S Ultra diffractometer at 294(1) K. Structures were solved using the SHELXS97 direct methods program. Molecular diagrams were generated using Mercury software. Starting materials were commercially obtained and used without further purification. Solvents used were of HPLC grade.
Caution! Nitrogen-rich compounds such as tetrazole derivatives are used as components for explosive mixtures. In our laboratory, the reactions described were run on a few gram scale, and no problems were encountered. However, great caution should be exercised when heating or handling compounds of this type.

### 5.5.2 Synthesis of Flexible Bis-Tetrazole Ligands 5.1, 5.2 and 5.3

### 5.5.2.1 1,3-bis(4-pyridyl)propane-N,N’-dioxide (5.8)

A mixture of 4, $4^{\prime}$-trimethylenedipyridine ( $6.00 \mathrm{~g}, 30.30 \mathrm{mmol}$ ), acetic acid ( 24 mL ), and $35 \% \mathrm{H}_{2} \mathrm{O}_{2}(12 \mathrm{~mL})$ was heated at $70-80^{\circ} \mathrm{C}$ for 3 h . An additional portion of $\mathrm{H}_{2} \mathrm{O}_{2}(9 \mathrm{~mL})$ was added and heating was continued for a further 9 h . The excess acetic acid and $\mathrm{H}_{2} \mathrm{O}$ were removed under reduced pressure. $\mathrm{H}_{2} \mathrm{O}(12 \mathrm{~mL})$ was introduced, and the mixture was concentrated to dryness under vacuum. Acetone ( 90 mL ) was added to the remaining oil to yield a white precipitate, which was filtered off and washed twice with hot acetone to remove unreacted 4,4'-trimethylenedipyridine. The crude product was recrystallised in EtOH to give 5.22 g of ligand ( $75 \%$ yield). m.p. $220-223{ }^{\circ} \mathrm{C}$. IR ( KBr ): $v=3089,3005,1501$, 1486, 1459, 1412, 1254, 1230, 1200, 1170, 1112, 1043, 890, 864, 812, 761, $576 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO): $\delta=8.11(\mathrm{~d}, 4 \mathrm{H}, J=6.7 \mathrm{~Hz}$, pyr-H), $7.27(\mathrm{~d}, 4 \mathrm{H}, J=6.7 \mathrm{~Hz}, \mathrm{pyr}-\mathrm{H}), 2.58(\mathrm{t}$, $4 \mathrm{H}, J=7.6 \mathrm{~Hz}$, pyr-CH2 ), 1.86 (quin, $2 \mathrm{H}, J=7.6 \mathrm{~Hz}, \mathrm{CH}_{2}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $d_{6}-\mathrm{DMSO}$ ): $\delta=$ 139.8 (pyr-C), 138.2 (pyr-CH), 126.3 (pyr-CH), 32.6 (pyr-CH $)_{2}$, $30.0\left(\mathrm{CH}_{2}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{13} \mathrm{H}_{15} \mathrm{~N}_{2} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}]^{+}$231.1128, found 231.1133.

The NMR and IR data are in agreement with the reported values. ${ }^{233}$

### 5.5.2.2 1,3-bis(4-pyridyl-3-cyano)propane (5.9)

To a suspension of $5.8(0.20 \mathrm{~g}, 0.87 \mathrm{mmol})$ in anhydrous DMF ( 20 mL ) was added $\mathrm{Zn}(\mathrm{CN})_{2}$ ( $0.31 \mathrm{~g}, 2.61 \mathrm{mmol}$ ). The mixture was stirred at room temperature under argon for 30 min before DMCC ( $0.32 \mathrm{~mL}, 3.47 \mathrm{mmol}$ ) was added dropwise at $0^{\circ} \mathrm{C}$ over 1 h . The reaction was then brought up to room temperature and stirred for $24 \mathrm{~h} .10 \%$ aqueous $\mathrm{K}_{2} \mathrm{CO}_{3}(10 \mathrm{~mL})$ was added to the solution and stirred for 15 min . The solution was then extracted with DCM ( $3 \times 10 \mathrm{~mL}$ ) and the combined organic extracts were washed with brine and dried over $\mathrm{MgSO}_{4}$. After removing the insoluble solids by filtration the volatiles were removed under reduced pressure to yield a brown oil. This crude product was passed through a silica plug using EtOAc and Pet. Ether (3:1) as the eluent and recrystallised from a mixture of DCM and Pet. Ether to yield a white crystalline solid ( $0.07 \mathrm{~g}, 34 \%$ ). m.p. $120-122^{\circ} \mathrm{C}$. IR (KBr): $v=3030,2921,2237,1597,1552,1462,1405,1384,1261,1147,1086,1069,1022$,

991, 902, $840,758 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta=8.63(\mathrm{~d}, 2 \mathrm{H}, J=5.0 \mathrm{~Hz}$, pyr-H), $7.54(\mathrm{~s}, 2 \mathrm{H}$, pyr-H), $7.34(\mathrm{~d}, 2 \mathrm{H}, \mathrm{J}=5.0 \mathrm{~Hz}$, pyr-H), $2.75(\mathrm{t}, 4 \mathrm{H}, J=7.8 \mathrm{~Hz}$, pyr-CH2 ), 2.03 (quin, $2 \mathrm{H}, J=$ $7.8 \mathrm{~Hz}, \mathrm{CH}_{2}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=151.6,151.2,134.2,128.5,126.8,117.2$ (CN), 34.2 (pyr- $\mathrm{CH}_{2}$ ), $30.1\left(\mathrm{CH}_{2}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{15} \mathrm{H}_{13} \mathrm{~N}_{4}[\mathrm{M}+\mathrm{H}]^{+}$249.1135, found 249.1140.

The NMR and IR data are in agreement with the reported literature values. ${ }^{232}$

### 5.5.2.3 1,3-bis(2-(2H-tetrazol-5-yl)pyridin-4-yl)propane (5.10)

5.9 ( $0.83 \mathrm{~g}, 3.34 \mathrm{mmol}$ ), $\mathrm{NaN}_{3}(0.48 \mathrm{~g}, 7.35 \mathrm{mmol}), \mathrm{NH}_{4} \mathrm{Cl}(0.39 \mathrm{~g}, 7.35 \mathrm{mmol})$ and LiCl $(0.07 \mathrm{~g}, 1.67 \mathrm{mmol})$ were heated to reflux in DMF ( 20 mL ) for 10 h . The inorganic solids were removed by filtration and the filtrate was concentrated under reduced pressure. The residue was then redissolved in deionised $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$ and acidified with 1 M HCl until precipitation ceased. The precipitate was filtered off and washed with deionised $\mathrm{H}_{2} \mathrm{O}$ and air dried. Yellow solid ( $1.04 \mathrm{~g}, 93 \%$ ). m.p. $220-223{ }^{\circ} \mathrm{C}$. IR ( KBr ): $v=3386,3042,2874$, 2777, 1597, 1633, 1613, 1562, 1493, 1484, 1406, 1384, 1261, 1149, 1086, 1069, 1024, 1000, 846, $760 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO): $\delta=8.66(\mathrm{~d}, 2 \mathrm{H}, J=5.1 \mathrm{~Hz}$, pyr-H), $8.09(\mathrm{~s}, 2 \mathrm{H}$, pyr-H), $7.50\left(\mathrm{~d}, 2 \mathrm{H}, J=5.1 \mathrm{~Hz}\right.$, pyr-H), $2.81(\mathrm{t}, 4 \mathrm{H}, J=7.8 \mathrm{~Hz}, \text { pyr-CH2})_{2}, 2.03$ (quin, $2 \mathrm{H}, J=$ $7.8 \mathrm{~Hz}, \mathrm{CH}_{2}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $d_{6}$-DMSO): $\delta=154.9\left(\mathrm{CN}_{4}\right), 152.9,149.8,143.7,126.0,122.5$, 33.7 (pyr- $\mathrm{CH}_{2}$ ), $29.9\left(\mathrm{CH}_{2}\right) \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{15} \mathrm{H}_{15} \mathrm{~N}_{10}[\mathrm{M}+\mathrm{H}]^{+} 335.1476$, found 335.1476.

### 5.5.2.4 Synthesis of 5.1, 5.2 and 5.3

$5.10(0.90 \mathrm{~g}, 2.69 \mathrm{mmol})$ and $\mathrm{K}_{2} \mathrm{CO}_{3}(0.78 \mathrm{~g}, 5.66 \mathrm{mmol})$ were heated to reflux for 30 min after which time ethyl bromoacetate ( $0.62 \mathrm{~mL}, 6.66 \mathrm{mmol}$ ) was added. The reaction was then further heated under reflux for 24 h . The solution was then cooled and filtered and the filtrate was concentrated under reduced pressure. The remaining brown oil consisted of three regioisomers which were separated by column chromatography, starting with 2:1 EtOAc:Pet. Ether and finishing with $100 \%$ EtOAc.

### 5.5.2.4.1 Diethyl 2,2'-(5,5'-(4,4'-(propane-1,3-diyl)bis(pyridine-4,2diyl) )bis(1H-tetrazole-5,1-diyl))diacetate (5.1)

Yellow solid ( $0.14 \mathrm{~g}, 10 \%$ ). m.p. $116-119^{\circ} \mathrm{C}$. IR (KBr): $v=2989,2960,1748,1603,1537$, 1479, 1462, 1431, 1403, 1379, 1298, 1230, 1118, 1030, $993,852 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta$ $=8.54(\mathrm{~d}, 2 \mathrm{H}, J=5.0 \mathrm{~Hz}$, pyr-H), $8.27(\mathrm{~s}, 2 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 7.26(\mathrm{~d}, 2 \mathrm{H}, J=5.0 \mathrm{~Hz}, \mathrm{pyr}-\mathrm{H}), 5.74(\mathrm{~s}$, $4 \mathrm{H}, \mathrm{CH}_{2}$-tet), $4.20\left(\mathrm{q}, 4 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{OCH}_{2}\right.$ ), $2.80\left(\mathrm{t}, 4 \mathrm{H}, J=7.7 \mathrm{~Hz}\right.$, pyr- $\mathrm{CH}_{2}$ ), 2.11 (quin, 2 $\left.\mathrm{H}, J=7.7 \mathrm{~Hz}, \mathrm{CH}_{2}\right), 1.20\left(\mathrm{t}, 6 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right): \delta=166.0(\mathrm{C}=0)$, 152.2 (pyr-C), 152.2 ( $\mathrm{CN}_{4}$ ), 149.3 (pyr-CH), 144.5 (C-CN4), 125.6 (pyr-CH), 124.0 (pyr-CH), $62.1\left(\mathrm{OCH}_{2}\right), 51.1\left(\right.$ tet- $\left.-\mathrm{CH}_{2}\right), 34.5\left(\right.$ pyr- $\left.\mathrm{CH}_{2}\right), 30.3\left(\mathrm{CH}_{2}\right), 14.0\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{23} \mathrm{H}_{27} \mathrm{~N}_{10} \mathrm{O}_{4}[\mathrm{M}+\mathrm{H}]^{+} 507.2211$, found 507.2232.

### 5.5.2.4.2 Ethyl 2-(5-(4-(3-(2-(1-(2-ethoxy-2-oxoethyl)-1H-tetrazol-5-yl)pyridin-4-yl)propyl)pyridin-2-yl)-2H-tetrazol-2-yl)acetate (5.2)

Yellow solid ( $0.21 \mathrm{~g}, 16 \%$ ). m.p. $58-60^{\circ} \mathrm{C}$. IR (KBr): $v=2930,1750,1733,1606,1560$, $1430,1387,1223,1118,1025,854,793 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.68(\mathrm{~d}, 1 \mathrm{H}, J=4.8 \mathrm{~Hz}$, pyr-H), 8.54 (d, $1 \mathrm{H}, \mathrm{J}=5.1 \mathrm{~Hz}$, pyr-H), 8.29 (s, 1 H, pyr-H), 8.11 ( $\mathrm{s}, 1 \mathrm{H}$, pyr-H), 7.24-7.27 ( $\mathrm{m}, 2 \mathrm{H}$, pyr-H), 5.74 (s, 2 H , tet- $\mathrm{CH}_{2}$ ), $5.50\left(\mathrm{~s}, 2 \mathrm{H}\right.$, tet- $\mathrm{CH}_{2}$ ), 4.28 ( $\mathrm{q}, 2 \mathrm{H}, 7.2 \mathrm{~Hz}, \mathrm{OCH}_{2}$ ), 4.19 ( $q, 2 \mathrm{H}, 7.2 \mathrm{~Hz}, \mathrm{OCH}_{2}$ ), 2.77-2.82 (m, 4 H, pyr- $\mathrm{CH}_{2}$ ), 2.07-2.17 (m, $2 \mathrm{H}, \mathrm{CH}_{2}$ ), $1.29(\mathrm{t}, 3 \mathrm{H}, J=$ $\left.7.2 \mathrm{~Hz}, \mathrm{CH}_{3}\right), 1.19\left(\mathrm{t}, 3 \mathrm{H}, J=7.2 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta=165.0,164.1,163.8$, 151.4, 151.2, 150.6, 149.4 (pyr-CH), 148.2 (pyr-CH), 145.5, 143.4, 124.6 (pyr-CH), 124.1 (pyr-CH), 123.0 (pyr-CH), 121.5 (pyr-CH), $61.7\left(\mathrm{OCH}_{2}\right), 61.0\left(\mathrm{OCH}_{2}\right), 52.5\left(\right.$ tet- $\left.\mathrm{CH}_{2}\right), 50.1$ (tet- $\mathrm{CH}_{2}$ ), 33.5 (pyr- $\mathrm{CH}_{2}$ ), $29.3\left(\mathrm{CH}_{2}\right), 13.1\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd for $\mathrm{C}_{23} \mathrm{H}_{2} \mathrm{~N}_{10} \mathrm{O}_{4}$ $[\mathrm{M}+\mathrm{H}]^{+} 507.2211$, found 507.2229.

### 5.5.2.4.3 Diethyl 2,2'-(5,5'-(4,4'-(propane-1,3-diyl)bis(pyridine-4,2-diyl))bis(2H-tetrazole-5,2-diyl))diacetate (5.3)

Orange solid ( 0.38 g , 28\%). m.p. $138-141^{\circ} \mathrm{C}$. IR (KBr): $v=2999,2956,1743,1632,1607$, 1559, 1523, 1479, 1419, 1387, 1370, 1348, 1222, 1053, 1021, 994, $840 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.68(\mathrm{~d}, 2 \mathrm{H}, \mathrm{J}=5.1 \mathrm{~Hz}$, pyr-H), $8.13(\mathrm{~s}, 2 \mathrm{H}, \mathrm{pyr}-\mathrm{H}), 7.24(\mathrm{~d}, 2 \mathrm{H}, \mathrm{J}=5.1 \mathrm{~Hz}$, pyrH), $5.50\left(\mathrm{~s}, 4 \mathrm{H}^{2} \mathrm{CH}_{2}\right.$-tet), $4.28\left(\mathrm{q}, 4 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{OCH}_{2}\right), 2.80\left(\mathrm{t}, 4 \mathrm{H}, J=7.7 \mathrm{~Hz}, \mathrm{pyr}^{2}-\mathrm{CH}_{2}\right)$, 2.13 (quin, $2 \mathrm{H}, J=7.7 \mathrm{~Hz}, \mathrm{CH}_{2}$ ), $1.28\left(\mathrm{t}, 6 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta=$ 165.0 (C=O), 164.8 ( $\mathrm{CN}_{4}$ ), 151.8 (pyr-C), 150.4 (pyr-CH), 146.5 (C-CN $\mathrm{C}_{4}$ ), 125.1 (pyr-CH), 122.6 (pyr-CH), $62.8\left(\mathrm{OCH}_{2}\right), 53.5($ tet-CH2 $), 34.6\left(\mathrm{pyr}-\mathrm{CH}_{2}\right), 30.5\left(\mathrm{CH}_{2}\right), 14.0\left(\mathrm{CH}_{3}\right) \mathrm{ppm}$. ESI-HRMS: calcd. for $\mathrm{C}_{23} \mathrm{H}_{27} \mathrm{~N}_{10} \mathrm{O}_{4}[\mathrm{M}+\mathrm{H}]^{+} 507.2211$, found 507.2198.

### 5.5.3 Synthesis of Rigid Bis-Tetrazole Ligands 5.4, 5.5 and 5.6

### 5.5.3.1 2,3-bis(1H-tetrazol-5-yl)pyrazine (5.12)

$\mathrm{NaN}_{3}(0.52 \mathrm{~g}, 8.07 \mathrm{mmol}), \mathrm{NH}_{4} \mathrm{Cl}(0.43 \mathrm{~g}, 8.07 \mathrm{mmol})$ and $\mathrm{LiCl}(0.08 \mathrm{~g}, 1.88 \mathrm{mmol})$ were added to a solution of 2,3-dicyanopyrazine ( $0.50 \mathrm{~g}, 3.84 \mathrm{mmol}$ ) in anhydrous DMF ( 20 mL ). The suspension was then heated at $110^{\circ} \mathrm{C}$ for 12 h , cooled to room temperature and filtered. The filtrate was then concentrated under reduced pressure. The residue was then dissolved in deionised $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$ and acidified with conc. HCl until precipitation initiated. The solids were then filtered off, washed with $\mathrm{H}_{2} \mathrm{O}$ and dried. The solid was recrystallised from hot EtOH to yield an orange crystalline solid ( $0.56 \mathrm{~g}, 67 \%$ ). IR ( KBr ): $v$ $=3418,2828,2855,1651,1601,1452,1278 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-DMSO) : $\delta=9.11(\mathrm{~s}, 2 \mathrm{H}$, pyz-H), $3.56(\mathrm{~s}, 2 \mathrm{H}, \mathrm{NH})$ ppm. ${ }^{13} \mathrm{C}$ NMR ( $d_{6}$-DMSO): $\delta=153.3\left(\mathrm{CN}_{4}\right), 146.1,139.8 \mathrm{ppm}$. ESIHRMS: calcd. for $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~N}_{10}[\mathrm{M}+\mathrm{H}]^{+}$217.0693, found 217.0698.

### 5.5.3.2 Synthesis of 5.4, $\mathbf{5 . 5}$ and $\mathbf{5 . 6}$

DIEA ( $8.46 \mathrm{~mL}, 48.60 \mathrm{mmol}$ ) was added to a suspension of $\mathbf{5 . 1 2}$ ( $3.50 \mathrm{~g}, 16.20 \mathrm{mmol}$ ) in MeCN ( 20 mL ) and the solution was heated to reflux for 1 h . After this time, ethyl bromoacetate ( $3.95 \mathrm{~mL}, 35.64 \mathrm{mmol}$ ) was added and the reaction was further heated to reflux for 24 h . The orange solution was then cooled to room temperature and concentrated under reduced pressure. The residue was then redissolved in DCM ( 30 mL ), washed with water ( $3 \times 15 \mathrm{~mL}$ ) and the organic extracts were dried over $\mathrm{MgSO}_{4}$. The volatiles were removed under reduced pressure. The three regioisomers were separated by recrystallisation of the residue in $\mathrm{CHCl}_{3}$, Pet. Ether and MeOH . Sequential filtration of the filtrate over time yielded the three purified products.

### 5.5.3.2.1 Ethyl 2-(5-(3-(1-(2-ethoxy-2-oxoethyl)-1H-tetrazol-5-yl)pyrazin-2-yl)-2H-tetrazol-2-yl)acetate (5.4)

White block crystals (1.46 g, 23\%). IR (KBr): v = 2997, 2953, 1757, 1745, 1470, 1443, 1417, 1406, 1373, 1350, 1300, 1276, 1249, 1220, 1154, 1101, 1023, 1014, 993, 892, 881, $808 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.94(\mathrm{~d}, 1 \mathrm{H}, J=2.3 \mathrm{~Hz}, \mathrm{pyz}-\mathrm{H}), 8.80(\mathrm{~d}, 1 \mathrm{H}, \mathrm{J}=2.3 \mathrm{~Hz}$, pyzH), 5.49 ( s, $2 \mathrm{H}, \mathrm{CH}_{2}$-tet), 5.47 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{CH}_{2}$-tet), $4.29\left(\mathrm{q}, 2 \mathrm{H}, J=7.2 \mathrm{~Hz}, \mathrm{OCH}_{2}\right.$ ), $4.19(\mathrm{q}, 2 \mathrm{H}, J$ $=7.2 \mathrm{~Hz}, \mathrm{OCH}_{2}$ ), $1.30\left(\mathrm{t}, 3 \mathrm{H}, J=7.2 \mathrm{~Hz}, \mathrm{CH}_{3}\right), 1.20\left(\mathrm{t}, 3 \mathrm{H}, J=7.2 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=165.1$ (C=0), 164.5 (C=0), 162.1, 150.8, 145.5, 144.1, 143.3, 139.9, 62.9, 62.6, 53.7, 49.9, 13.9 ppm. ESI-HRMS: calcd. for $\mathrm{C}_{14} \mathrm{H}_{17} \mathrm{~N}_{10} \mathrm{O}_{4}[\mathrm{M}+\mathrm{H}]^{+} 389.1429$, found 389.1416.

### 5.5.3.2.2 Diethyl 2,2'-(5,5'-(pyrazine-2,3-diyl)bis(1H-tetrazole-5,1diyl))diacetate (5.5)

White needle like crystals ( $0.64 \mathrm{~g}, 10 \%$ ). IR ( KBr ): $v=2943,1750,1634,1466,1440,1418$, 1396, 1376, 1264, 1231, 1147, 1094, 1031, 884, 799, $772 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta=8.85$ (s, 2 H, pyz-H), 5.47 (s, $4 \mathrm{H}, \mathrm{CH}_{2}$-tet), $4.21\left(\mathrm{q}, 4 \mathrm{H}, J=7.2 \mathrm{~Hz}, \mathrm{OCH}_{2}\right.$ ), $1.23(\mathrm{t}, 6 \mathrm{H}, J=7.2 \mathrm{~Hz}$, $\left.\mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=165.1(\mathrm{C}=0), 150.5\left(\mathrm{CN}_{4}\right), 144.7,140.9,148.9,62.7\left(\mathrm{CH}_{2}-\right.$ tet), $49.9\left(\mathrm{OCH}_{2}\right), 14.0\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{14} \mathrm{H}_{17} \mathrm{~N}_{10} \mathrm{O}_{4}[\mathrm{M}+\mathrm{H}]^{+} 389.1429$, found 389.1434.

### 5.5.3.2.3 Diethyl 2,2'-(5,5'-(pyrazine-2,3-diyl)bis(2H-tetrazole-5,2diyl))diacetate (5.6)

White needle like crystals ( $0.55 \mathrm{~g}, 9 \%$ ). IR ( KBr ): $v=2980,1745,1416.1371,1341,1233$, 1075, 1017, $876 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=8.90(\mathrm{~s}, 2 \mathrm{H}, \mathrm{pyz}-\mathrm{H}), 5.46\left(\mathrm{~s}, 4 \mathrm{H}, \mathrm{CH}_{2}\right.$-tet), 4.27 ( $\mathrm{q}, 4 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{OCH}_{2}$ ), $1.29\left(\mathrm{t}, 6 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta=164.6$ (C=O), $162.6\left(\mathrm{CN}_{4}\right), 145.0,142.4,62.8\left(\mathrm{CH}_{2}\right.$-tet), $53.5\left(\mathrm{OCH}_{2}\right), 14.0\left(\mathrm{CH}_{3}\right)$ ppm. ESI-HRMS: calcd. for $\mathrm{C}_{14} \mathrm{H}_{17} \mathrm{~N}_{10} \mathrm{O}_{4}[\mathrm{M}+\mathrm{H}]^{+} 389.1429$, found 389.1438.

### 5.5.4 Metal Complexation Reactions with 5.1 and 5.2

### 5.5.4.1 $\left[\mathrm{Cu}(5.1) \mathrm{Cl}_{2}\right]_{\mathrm{n}}(5.13)$

5.1 ( $0.04 \mathrm{~g}, 0.08 \mathrm{mmol}$ ) was dissolved in EtOH ( 15 mL ). $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}(0.01 \mathrm{~g}, 0.08 \mathrm{mmol})$ in EtOH ( 5 mL ) was added to the solution. The resulting mixture was heated to reflux for 2 h , cooled to room temperature and filtered. Green solid ( $0.03 \mathrm{~g}, 59 \%$ ). $\mathrm{C}_{23} \mathrm{H}_{26} \mathrm{Cl}_{2} \mathrm{CuN}_{10} \mathrm{O}_{4}$ : calcd. C 43.10, H 4.09, N 21.85\%; found C 43.85, H 4.11, N 21.99\%. IR (KBr): v = 3414, 2961, 1747, 1637, 1622, 1554, 1481, 1490, 1459, 1430, 1401, 1376, 1342, 1296, 1249, 1219, 1116, 1013, 867, 852, $623 \mathrm{~cm}^{-1}$. Magnetic moment: 1.92 B.M.

### 5.5.4.2 [Cu2(5.2)Cl 4$]_{n}(5.14)$

5.2 ( $0.10 \mathrm{~g}, 0.20 \mathrm{mmol}$ ) was dissolved in EtOH ( 20 mL ). $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}(0.03 \mathrm{~g}, 0.20 \mathrm{mmol})$ in EtOH ( 5 mL ) was added to the solution. The resulting mixture was heated to reflux for 2 h , cooled to room temperature and filtered. Green solid ( $0.07 \mathrm{~g}, 92 \%$ ). $\mathrm{C}_{23} \mathrm{H}_{26} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{4}$ : calcd. C 35.63 , H 3.38, N 18.06\%; found C 35.98, H 3.69, N 18.09\%. IR (KBr): v = 3440, 2982, 2938, 1750, 1622, 1565, 1475, 1440, 1397, 1372, 1347, 1262, 1220, 1063, 1019, 874, 853, 771, $580 \mathrm{~cm}^{-1}$. Magnetic moment: 1.78 B.M.

### 5.5.5 Metal Complexation Reactions of 5.4 and 5.5

### 5.5.5.1 $\left[\mathrm{Cu}(5.4)\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]_{\mathrm{n}}(5.15)$

5.4 ( $0.10 \mathrm{~g}, 0.26 \mathrm{mmol})$ was suspended in deionised $\mathrm{H}_{2} \mathrm{O}$ ( 15 mL ). $\mathrm{NaOH}(0.02 \mathrm{~g}, 0.52$ $\mathrm{mmol})$ was added and the mixture was heated under reflux for $2 \mathrm{~h} . \mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}(0.04 \mathrm{~g}$, 0.26 mmol ) was added in deionised $\mathrm{H}_{2} \mathrm{O}$ and the solution was cooled slowly and allowed to stand for several days. The resulting solids were filtered off and washed with deionised $\mathrm{H}_{2} \mathrm{O}$. Blue crystalline solid ( $0.07 \mathrm{~g}, 60 \%$ ). $\mathrm{C}_{10} \mathrm{H}_{8} \mathrm{CuN}_{10} \mathrm{O}_{5} .2 \mathrm{H}_{2} \mathrm{O}$ : calcd. C 26.82 , H 2.70, N 31.28\%; found C 26.59, H 2.66, N 31.48\%. IR (KBr): $v=3419,3001,1660,1636,1480$, $1433,1377,1353,1328,1305,1216,1176,1108,1087,1032,879,821,751,718,691,547$ $\mathrm{cm}^{-1}$. Magnetic moment: 1.96 B.M.

### 5.5.5.2 $\left[\mathrm{Cu}(5.5)\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]_{\mathrm{n}}(5.16)$

$5.5(0.03 \mathrm{~g}, 0.08 \mathrm{mmol})$ was suspended in deionised $\mathrm{H}_{2} \mathrm{O}(6 \mathrm{~mL}) . \mathrm{NaOH}(6 \mathrm{mg}, 0.16 \mathrm{mmol})$ was added to the mixture and the reaction was heated under reflux for $2 \mathrm{~h} . \mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ ( $0.03 \mathrm{~g}, 0.16 \mathrm{mmol}$ ) in deionised $\mathrm{H}_{2} \mathrm{O}$ was added to the solution which was then cooled slowly. A blue crystalline solid formed ( $0.02 \mathrm{~g}, 49 \%$ ) which was filtered off and washed with deionised $\mathrm{H}_{2} \mathrm{O} . \mathrm{C}_{10} \mathrm{H}_{6} \mathrm{CuN}_{10} \mathrm{O}_{4} .2 \mathrm{H}_{2} \mathrm{O}$ : calcd. C 27.95, H $2.35, \mathrm{~N} 32.59 \%$; found C $28.24, \mathrm{H}$
3.03, $\mathrm{N} 32.08 \%$. IR (KBr): $v=3524,3050,1640,1452,1422,1380,1304,1149,1125,1101$, 1032, 955, 889, 955, 889, 819, 718, 682, 590, 553, 454, $384 \mathrm{~cm}^{-1}$. Magnetic Moment: 2.11 B.M.

## Chapter 6: Conclusions and Future Work

### 6.1 Conclusions

This thesis comprises a collection of molecular assemblies based on heteroaryl tetrazole ligands. To address the first goal of the work carried out in this thesis, the synthesis and characterisation of an array of novel ligands were described. The synthesis of these ligands was facile; an aspect which is useful as easy access to a huge library of derivatives is key in the efficient determination of structure-activity relationships. All ligands were subjected to complexation reactions resulting in the formation and characterisation of novel coordination complexes. Copper(II), nickel(II), zinc(II) and cobalt(II) metal salts were employed in these complexation reactions. These complexes were prepared in moderate to good yields and remained stable for an extended period. In vivo toxicity studies in $G$. mellonella larvae on two complexes which showed promising anti-cancer activity revealed a high tolerance to the complexes, which is a promising result considering the positive correlations between $G$. mellonella larvae studies and mammalian studies in mice. These complexes and free ligands are intended to be investigated further for their anti-cancer activities through the US National Cancer Institute which will yield useful information on their mechanisms of action and will contribute to the direction of future efforts in the area of cancer chemotherapy.

In Chapter 3, the pyridyl tetrazole chelating unit was exploited further, in the production of coordination networks and coordination polymers. This was achieved by substituting the tetrazole ring with an ethyl ester group, which was capable of forming a carboxylate in situ, which prevented the ligand from behaving as a terminal coordinating ligand and allowed it to act as a bridging ligand. These derivatives were reacted with copper(II), zinc(II), nickel(II) and cobalt(II) metal salts in different ratios of water methanol solutions. This work produced X-ray crystal structures of products obtained in copper (II) chloride reactions. This analysis revealed that solvent composition was an important parameter as 1-D extended structures were obtained in solutions with a higher percentage of methanol, and coordination networks and dinuclear clusters were obtained in the cases where water was employed as reaction solvent with $\mathrm{Cu}(\mathrm{II})$ pyridyl tetrazole subunits hydrogen bonding to neighbouring subunits. The position of the ester group on the tetrazole ring also had an effect on the final structures. The ligands acted as either bridging linkers with coordination occurring through both nitrogens and carboxylate oxygens (3.10, 3.11) or terminal ligands coordinating through either nitrogens only (3.13) or carboxylate oxygens only (3.11). This work also resulted in the formation of Zn (II) coordination polymers and discrete complexes which were subjected to solid state fluorescence studies. This
demonstrated the potential for the use of these products and their derivatives as light emitting materials. Overall, we showed that carboxylate functionalised pyridyl tetrazole derivatives were useful as bridging ligands in coordination polymers. However, improvements to these linkers were required as in some cases the ligand was acting as a terminal ligand and thus prevented the extension of the frameworks and the opportunity to obtain higher dimensional structures.

Chapter 4 attempted to address these issues by synthesising ligands with an in situ generated carboxylate moiety on both the tetrazole and pyridine rings. This was proposed to enhance the ligands' ability to extend in three directions, thereby forming 3-D extended structures. Although we were unsuccessful in producing coordination polymers of high dimensionality, our investigations have led to the production of four novel 1-D coordination polymers and three dinuclear cluster formations. These products are structurally very interesting. The structural formations were affected by the position of the carboxylate group on the tetrazole ring, with extended structures being formed when using the $\mathrm{N}-1$ substituted ligand and dinuclear clusters forming as a result of employing the $\mathrm{N}-2$ substituted ligand. The choice of metal ion did not seem to have any effect on the final structures as isomorphic structures were obtained when using either of the ligands. The presence of an uncomplexed ionic carboxylate was detrimental in terms of forming higher dimensional structures, however this structural aspect does open avenues of carrying out post-synthetic modifications on the products. The ligands also displayed a high capacity for manipulation, as employing a harder metal ion (Mn(II)) coordinated to this free carboxylate group but left the alternate tetrazole carboxylate coordinatively free. This study also presented a different mode of carboxylate binding (bridging) that was not encountered up to this point in these investigations. The scope for manipulation was also demonstrated in the selective hydrolysis of the alkyl ester over the aromatic ester. The 1-D coordination polymer synthesised in this investigation again provides scope for covalent post-synthetic modifications. Therefore, the manipulation of these interesting structural aspects could provide an interesting topic of study in future explorations. The behaviour of these ligands also displayed a striking resemblance to bipy dicarboxylic derivatives. Thus, the novel building units reported in this work could provide analogs to the ubiquitous bipy molecules and comparative studies on the properties of the resulting frameworks could yield interesting results.

The theme of attempting to form high dimensional coordination polymers was continued in Chapter 5, with bis-tetrazole systems being considered as potential linkers in the
formation of frameworks with potential voids. Carboxylate functionalised pyridyl tetrazole units (like those discussed in Chapter 3) were linked by a trimethylene chain through the pyridine moieties. These were then reacted with metal salts in both the ester and carboxylate forms. These studies led to the formation of polymeric materials that were in the form of amorphous powders. The difficulty in attaining X-ray quality crystals hampered the accurate structural assignment of these products, which theoretically could produce a variety of products due to the conformational freedom of the starting ligands. Future work would involve the employment of different synthetic methods in order to obtain crystalline products. This is an area worthy of further investigation as the power of flexible based coordination polymers have only begun to be harnessed and promise a wealth of applications. The utilisation of rigidly linked tetrazole rings in coordination polymer synthesis yielded interesting results. Synthesis of the pyrazine linked carboxylate functionalised tetrazoles was easily achieved, however clean separation of the regioisomers was a laborious task. In contrast to the flexible ligands discussed above, the reaction of two of these regioisomers with copper(II) chloride in aqueous sodium hydroxide solution yielded blue crystalline products which were suitable for X-ray crystallography. The use of these ligands achieved our aim of obtaining higher dimensional extended frameworks, with 2-D coordination polymers forming. We reported the formation of a coordination polymer that exhibited an interesting pocket where water clusters resided (5.15). The topic of stabilised water clusters continuously generates considerable interest among both theoretical and experimental chemists. Crystal lattice host environments such as those provided by MOFs are increasingly being exploited for quantitative characterisation of the hydrogen bonded networks that exist in aqueous solution. These hydrophilic environments also raise the possibility of encapsulation of biomolecules. A proof of concept could be achieved by encapsulating a simple sugar molecule or polar amino acid into the hydrophilic pockets. The motivation behind the increased interest in encapsulating biomolecules is the desire to control the functions, properties and the stability of the trapped molecules.

In addition to the previously mentioned opportunities for future development, the addition of secondary ligands in the synthesis of these frameworks, such as 4,4'bipyridine, could lead to connection of the layers, thereby forming 3-D architectures. The use of the free tetrazole derivatives synthesised in this work as organic linkers also offers an attractive and under investigated avenue of research.

In summary, a small contribution to the fields of medicinal chemistry and coordination polymers has been achieved. We have proven that heteroaryl tetrazole ligands are extremely useful and versatile in the construction of discrete and extended molecular aggregates.

## Appendix

## Appendix A: Crystal Structure Data

Table A1: Crystal data and structure refinement for crystal structures.

|  | 2.67 | 2.71 | 3.1 |
| :---: | :---: | :---: | :---: |
| Chemical formula | $\mathrm{C}_{22} \mathrm{H}_{26} \mathrm{CoN}_{12} \mathrm{~S}_{2}$ | $\mathrm{C}_{30} \mathrm{H}_{42} \mathrm{CoN}_{12} \mathrm{~S}_{2}$ | $\mathrm{C}_{10} \mathrm{H}_{11} \mathrm{~N}_{5} \mathrm{O}_{2}$ |
| $M_{r}$ | 581.60 | 693.81 | 233.24 |
| Crystal system, space group | Orthorhombic, $\mathrm{Pca2}_{1}$ | Monoclinic, $P 2_{1} / \mathrm{c}$ | Triclinic, $P^{-1}$ |
| Temperature (K) | 294(1) | 294(1) | 294(2) |
| $a, b, c$ (Å) | $\begin{array}{\|l\|} \hline 15.9466(4), \\ 8.4530(2), \\ 20.6129(5) \\ \hline \end{array}$ | $\begin{array}{\|l} \hline 13.5506(10), \\ 8.4428(5), \\ 15.9122(10) \\ \hline \end{array}$ | $\begin{array}{\|l\|} \hline 9.3222(18), \\ 9.591(2), \\ 14.147(3) \\ \hline \end{array}$ |
| $V\left(\AA^{3}\right)$ | 2778.55 (12) | 99.063 (7) | 1167.3 (4) |
| $z$ | 4 | 1797.7 (2) | 4 |
| $\mu\left(\mathrm{mm}^{-1}\right)$ | 0.80 | 2 | 0.10 |
| Crystal size (mm) | $0.39 \times 0.22 \times 0.10$ | $0.36 \times 0.36 \times 0.07$ | $0.26 \times 0.26 \times 0.08$ |
| $T_{\text {min }}, T_{\text {max }}$ | $0.745,0.924$ | 0.804, 0.957 | - |
| No. of measured, independent and observed reflections | $\begin{array}{\|l} \hline 14564, \\ 5529, \\ 4007 \\ \hline \end{array}$ | $\begin{array}{\|l} 17401, \\ 4759, \\ 3108 \\ \hline \end{array}$ | $\begin{array}{\|l} 8885, \\ 5053, \\ 2449 \\ \hline \end{array}$ |
| Rint | 0.026 | 0.046 | 0.054 |
| $(\sin \theta / \lambda)_{\text {max }}\left(\AA^{-1}\right)$ | 0.658 | 0.694 | 0.658 |
| $R\left[F^{2}>2 \sigma\left(F^{2}\right)\right], w R\left(F^{2}\right), S$ | 0.052, 0.132, 1.04 | 0.080, 0.199, 1.12 | 0.065, 0.178, 1.03 |
| No. of reflections | 5529 | 4759 | 5053 |
| No. of parameters | 337 | 224 | 310 |
| No. of restraints | 37 | 5 | 0 |
| H -atom treatment | H-atom parameters constrained | H -atom parameters constrained | H atoms treated by a mixture of independent and constrained refinement |
| $\Delta \rho_{\text {max }}, \Delta \rho_{\text {min }}\left(\mathrm{e} \AA^{-3}\right)$ | 0.41, -0.22 | 0.34, -0.22 | 0.17, -0.19 |

|  | 3.8 | 3.9 | 3.10 |
| :---: | :---: | :---: | :---: |
| Chemical formula | $\mathrm{C}_{20} \mathrm{H}_{22} \mathrm{Cl}_{4} \mathrm{Cu}_{2} \mathrm{~N}_{10} \mathrm{O}_{4}$ | $\mathrm{C}_{20} \mathrm{H}_{22} \mathrm{Cl}_{2} \mathrm{CuN}_{10} \mathrm{O}_{4}$ | $\mathrm{C}_{16} \mathrm{H}_{12} \mathrm{CuN}_{10} \mathrm{O}_{4}$ |
| $M_{r}$ | 735.38 | 600.93 | 471.91 |
| Crystal system, space group | Triclinic, $P^{-1}$ | Monoclinic, $P 2_{1} / \mathrm{c}$ | Triclinic, $P^{-1}$ |
| Temperature (K) | 294(1) | 294(1) | 294(1) |
| $a, b, c$ (Å) | $\begin{aligned} & \hline 7.3592(4), \\ & 9.3625(16), \\ & 11.3789(6) \\ & \hline \end{aligned}$ | $\begin{array}{\|l\|} \hline 12.1566(2), \\ 13.9335(2), \\ 7.9649(2) \\ \hline \end{array}$ | $\begin{array}{\|l\|} \hline 6.7133(10), \\ 8.5824(10), \\ 8.6551(15) \\ \hline \end{array}$ |

## Appendix B: EPR Spectroscopy Hamiltonian Equation

Fitting of EPR spectra was performed by Dr. Høgni Weihe in the University of Copenhagen. As the EPR spectra revealed no signature of metal-metal interactions, the spectra were fitted to the spin Hamiltonian

$$
{ }^{\wedge} H=A x^{\wedge} S x^{\wedge} I x+A y^{\wedge} S y^{\wedge} I y+A z^{\wedge} S z^{\wedge} I z+{ }_{-} B\left(g x^{\wedge} S x B x+g y^{\wedge} S y B y+g z^{\wedge} S z B z\right)
$$

being appropriate for mononuclear $\mathrm{Cu}^{2+}$ spin systems with quantum numbers $(\mathrm{S} ; ~ I)=(1 / 2$, $3 / 2$ ). The parameters $A_{\mathrm{x}}$ and $A_{y}$ could not be determined from the broad lines, and $A_{z}$ could be reliably estimated for compounds 3.8, 3.10 and 3.11.
